Light transmission through a triangular air gap

Silvânia A. Carvalho and Stefano De Leo*

Department of Applied Mathematics, State University of Campinas, Brazil

(Received 22 January 2013; final version received 2 March 2013)

Due to the recent interest in studying propagation of light through triangular air gaps, we calculate, by using the analogy between optics and quantum mechanics and the multiple step technique, the transmissivity through a triangular air gap surrounded by an homogeneous dielectric. The new formula is then compared with the formula used in the literature. Starting from the qualitative and quantitative differences between these formulas, we propose optical experiments to test our theoretical results.

Keywords: laser; light transmission; stratified media

1. Introduction

Propagation of light through rectangular air gaps situated between homogeneous media is surely one of the most intriguing phenomenon of optics [1–3]. Although studied for a hundred years [4–6], it still represents a matter of early polarized with its electric and magnetic vector perpendicular to the incidence plane, the so-called transverse electric (TE) and magnetic (TM) waves [1]. The incidence angle which tends to the critical angle and we can use for the transmissivity

\[ T_{\triangle}^{(s,p)} \rightarrow \] 

\[ \left[ 1 + (n^2 - 1)\beta^2(L_s/\lambda)^2 \right]^{-1} s\text{-waves}, \]

\[ \left[ 1 + (n^2 - 1)(\pi/n^2)^2(L_s/\lambda)^2 \right]^{-1} p\text{-waves}. \]

In this case, for \( L_s \gg \lambda \) no light is transmitted in the second dielectric block. Decreasing the value of \( L_s \) up to several wavelengths, waves pass through the air interspace and light is transmitted in the second dielectric block. Due to the fact that varying the thickness of an air gap with precision is a very hard task, it has been proposed to study the transmission through a triangular air gap [8]. This allows one, by changing the incidence point of the light on the first dielectric/air interface, \( h \), to study the propagation through air gaps of different thickness, see Figure 1(b). Observing that the transmission probability is highly sensitive to the air gap between the dielectric blocks, coherence phenomena can be seen only for very small angles, i.e. \( \psi \ll 1 \). The distance between the dielectric blocks, \( L_s \), can be then approximated by \( h\psi \) and we can use for the transmissivity through a triangular air gap the following formula [13],

\[ T_{\triangle}^{(s,p)} := T_{\triangle}^{(s,p)} \] 

\[ [L_s \rightarrow h\psi]. \]

For \( n^2\sin^2\theta_s < 1 \), the incident beam is in general divided between two secondary beams. Nevertheless, there is a situation in which we have only the transmitted beam. The phenomenon of total transmission happens when \( h \) is an integer multiple of \( \lambda /2\psi(1 - n^2\sin^2\theta_s)^{1/2} \). For \( n^2\sin^2\theta_s \to 1 \), the triangular air gap acts as a frequency filter and only wavelengths of the order of \( h\psi \) are transmitted from the first to the second dielectric block.

new the multiple step calculation and give the

Figure 1. Geometric layout for the light propagation through
(a) rectangular and (b) triangular air gaps situated between
homogeneous media of refractive index \(n\).

The formulas used for the transmission of light through three layers, see Equation (1), are classical formulas. It is highly desirable to find a quantum analog. Starting from the analogy between optics [1–3] and quantum mechanics [19,20] and by using the multiple step technique [21–23], we calculate the propagation of an electromagnetic wave through a triangular air gap. Then, for \(\varphi \ll 1\), we analyze the differences between the new formula and the approximated one given in Equation (3) and used in the literature [13].

The paper is structured as follows. In Section 2, we discuss the analogies between light interaction upon the dielectric/air interface and the step potential in non-relativistic quantum mechanics (NRQM). In Section 3, for the convenience of the reader, we briefly review the multiple step calculation [21–24] which leads, for a rectangular air gap, to the transmission amplitude given in Equation (1). In Section 4, we consider \(\varphi\)-rotation of the second interface in the multiple step calculation and give the new transmission formula. In the final section, we draw our conclusions. In particular, we shall compare our formula with the formula used in the literature, Equation (3), and propose optical experiments for testing the new formula.

2. Analogy between optics and quantum mechanics

In this section, we present the connection between optical and quantum mechanics problems. In particular, we show how the NRQM formalism can be easily used to obtain the well-known Fresnel formulas for reflection and transmission of \(s\) and \(p\) polarized light. This connection will be fundamental for the calculation of the transmission probabilities done in the following sections.

Let us consider the plane \(x = 0\) as the incidence plane. The incident ray travels in the first dielectric block of refractive index \(n\) along the \(z\)-axis,

\[ q = nk\hat{z}. \]

In terms of the new \(y_s-z_s\) axes, the incident wave number can be rewritten as follows

\[
\begin{pmatrix}
q_y \\
n (z_s) = n \text{ for } z_s < d_s, \\
n \text{ for } z_s > d_s.
\end{pmatrix}
\]

This equation, by taking the correspondence

\[ n(z_s) = \frac{2m[E - V(z_s)]^{1/2}}{kh}, \]

\[ V(z_s) = \begin{cases} V_0 & \text{for } z_s < d_s, \\ 0 & \text{for } z_s > d_s, \end{cases} \]

exactly mimics the NRQM step potential dynamics [19]. This is obviously a mathematical analogy. The Maxwell and Schrödinger equations describe a different physics and such equations only coincide, in their mathematical description, for special cases. This correspondence is, for example, not exact for TM waves. As will be shown later, for TM waves we obtain the Fresnel formulas by introducing a translation rule. The TE incident and reflected beams which move in the first dielectric block, \(z_s < d_s\), are represented by the wave function

\[
\psi^{(s)}_< = \left\{ \exp[iq_x z_s] + r^{(s)} \exp[-iq_x z_s] \right\} \exp[iq_y y_s],
\]

where \(q_x\) and \(q_z\) are the wave number components of the beam which propagates in the first dielectric block. The transmitted beam which moves in the air gap, \(z_s > d_s\), is represented by

\[
\psi^{(s)}_\pi = r^{(s)} \exp[ip_z z_s] \exp[ip_y y_s],
\]
$p_y$ and $p_z$ are now the wave number components of the beam which propagates in the air gap. Being the discontinuity along the $z_a$ axis, the $y_a$ component of the wave number does not change passing from the dielectric to air, i.e. $p_y = q_y = nk \sin \theta_e$. This implies

$$p_z = k \left(1 - n^2 \sin^2 \theta_e \right)^{1/2}.$$  \hfill (6)

From the matching conditions, $\Psi_+(z_a = d_a) = \Psi_+(z_a = d_s)$ and $\Psi_-(z_a = d_s) = \Psi_-(z_a = d_e)$, we find [25]

$$r^{(s)}[q_{zs}, p_{zs}, d_s] = \frac{q_{zs} - p_{zs}}{q_{zs} + p_{zs}} \exp[2i(q_{zs}d_s)],$$

$$t^{(s)}[q_{zs}, p_{zs}, d_s] = \frac{2q_{zs}}{q_{zs} + p_{zs}} \exp[i(q_{zs} - p_{zs})d_s]. \hfill (7)$$

The Fresnel formulas are immediately obtained from the previous amplitudes,

$$R^{(s)} = |r^{(s)}|^2 = \left(\frac{n \cos \theta_e - (1 - n^2 \sin^2 \theta_e)^{1/2}}{n \cos \theta_e + (1 - n^2 \sin^2 \theta_e)^{1/2}} \right)^2,$$

$$T^{(s)} = \frac{p_{zs}}{q_{zs}} |r^{(s)}|^2 = \frac{4n \cos \theta_e(1 - n^2 \sin^2 \theta_e)^{1/2}}{(n \cos \theta_e + (1 - n^2 \sin^2 \theta_e)^{1/2})^2}. \hfill (8)$$

For $n \sin \theta_e \rightarrow 1$, $p_{zs}$ tends to zero and we have total reflection, $|r^{(s)}| = 1$. The reflection and transmission amplitudes for TM waves can be obtained by using the following translation rules,

$$r^{(p)}[q_{zs}, p_{zs}, d_s] = r^{(s)}\left[\frac{q_{zs}}{n}, np_{zs}, 0\right] \exp(2i(q_{zs}d_s)),$$

$$t^{(p)}[q_{zs}, p_{zs}, d_s] = t^{(s)}\left[\frac{q_{zs}}{n}, np_{zs}, 0\right] \exp[i(q_{zs} - p_{zs})d_s]. \hfill (9)$$

For $n \sin \theta_e < 1$, the incident beam is, in general, partially reflected and transmitted with intensities

$$R^{(p)} = |r^{(p)}|^2 = \left(\frac{\cos \theta_e - n(1 - n^2 \sin^2 \theta_e)^{1/2}}{\cos \theta_e + n(1 - n^2 \sin^2 \theta_e)^{1/2}} \right)^2,$$

$$T^{(p)} = n^2 \frac{p_{zs}}{q_{zs}} |r^{(p)}|^2 = \frac{4n \cos \theta_e(1 - n^2 \sin^2 \theta_e)^{1/2}}{(n \cos \theta_e + (1 - n^2 \sin^2 \theta_e)^{1/2})^2}. \hfill (10)$$

For a particular angle,

$$\sin \theta_B^B = 1/(n^2 + 1)^{1/2},$$

known as Brewster’s angle [1–3], we have $q_{zs} = n^2p_{zs}$, which implies $R^{(p)} = 0$ and, consequently, the incident light is totally transmitted.

3. Multiple step analysis for a rectangular air gap

It was demonstrated in previous works [14,15] that the transmission and reflection amplitudes of a rectangular (air) interspace can be built up by successive application of the step analysis [21–24]. As illustrated in Figure 2, at the first dielectric/air surface, $z_a = 0$, the incident wave is divided into two plane waves. The transmitted wave with amplitude $t^{(s,p)}[q_{zs}, p_{zs}, 0]$ moves through the air gap and after touching the second air/dielectric surface, $z_a = L_a$, will be transmitted with amplitude

$$t^{(s,p)}[q_{zs}, p_{zs}, 0]r^{(s,p)}[p_{zs}, q_{zs}, L_a].$$

This represents the first contribution to transmission through the rectangular air gap. The complete transmission amplitude is built up by considering the loop factor obtained by multiplying the amplitude of the reflected wave at the second air/dielectric surface by the one of the reflected wave at the first air/dielectric surface,

$$r^{(s,p)}[p_{zs}, q_{zs}, L_a]r^{(s,p)}[-p_{zs}, -q_{zs}, 0].$$

If it overlaps dominate, a single beam is transmitted and in order to find the transmission amplitude we have to sum all coherent multiple contributions,

$$t^{(s,p)}[q_{zs}, p_{zs}, 0]t^{(s,p)}[p_{zs}, q_{zs}, L_a]$$

$$\times \left\{ r^{(s,p)}[p_{zs}, q_{zs}, L_a]r^{(s,p)}[-p_{zs}, -q_{zs}, 0]\right\}^m$$

$$= \frac{t^{(s,p)}[q_{zs}, p_{zs}, 0]t^{(s,p)}[p_{zs}, q_{zs}, L_a]}{1 - r^{(s,p)}[p_{zs}, q_{zs}, L_a]r^{(s,p)}[-p_{zs}, -q_{zs}, 0]} \hfill (11)$$

![Figure 2. Multiple step analysis for light propagation through a rectangular air gap. This system represents the optical counterpart of the barrier potential problem in NRQM.](image-url)
Let us first calculate the transmissivity for the case of TE waves. Observing that
\[
\begin{align*}
\tilde{t}^{(t)}_{\tilde{\Delta}} &= 4q_{\tilde{z}}p_{\tilde{z}}\exp(-iq_{\tilde{z}}L)\left[(q_{\tilde{z}} + p_{\tilde{z}})^2\exp(-ip_{\tilde{z}}L) - (q_{\tilde{z}} - p_{\tilde{z}})^2\exp(ip_{\tilde{z}}L)\right]^{-1} \\
&= \exp(-iq_{\tilde{z}}L)\left[\cos(p_{\tilde{z}}L) - \frac{1}{2} \frac{q_{\tilde{z}}^2 + p_{\tilde{z}}^2}{2q_{\tilde{z}}p_{\tilde{z}}} \sin(p_{\tilde{z}}L)\right]^{-1},
\end{align*}
\]
we have
\[
T^{(t)}_{\Delta} = \left|\tilde{t}^{(t)}_{\Delta}\right|^2 = \left[1 + \left(\frac{q_{\tilde{z}}^2 - p_{\tilde{z}}^2}{2q_{\tilde{z}}p_{\tilde{z}}}\right)^2 \sin^2(p_{\tilde{z}}L)\right]^{-1}.
\]
A simple calculation shows that
\[
\frac{(q_{\tilde{z}}^2 - p_{\tilde{z}}^2)^2}{4q_{\tilde{z}}^2p_{\tilde{z}}^2} = \frac{(n^2 - 1)^2}{4n^2\cos^2\theta_s(1 - n^2\sin^2\theta_s)} = \alpha^{(s)}_{\Delta},
\]
and, consequently, we reproduce Equation (1) for s-polarized waves. In a similar way, observing that
\[
\begin{align*}
T^{(s)}_{\Delta} &= \left[1 + \left(\frac{q_{\tilde{z}}^2/n^2 - n^2p_{\tilde{z}}^2}{2q_{\tilde{z}}p_{\tilde{z}}}\right)^2 \sin^2(p_{\tilde{z}}L)\right]^{-1},
\end{align*}
\]
and
\[
\frac{(q_{\tilde{z}}^2/n^2 - n^2p_{\tilde{z}}^2)^2}{4q_{\tilde{z}}^2p_{\tilde{z}}^2} = \frac{(\cos^2\theta_s - n^2 + n^2\sin^2\theta_s)^2}{4\cos^2\theta_s(1 - n^2\sin^2\theta_s)} = \alpha^{(p)}_{\Delta},
\]
we obtain Equation (1) for TM waves.

4. Transmission through a triangular air gap

For the first dielectric/air interface, the computation of the transmissivity through the triangular air gap follows the calculation done in the previous section. For the second discontinuity, we have to observe that the second dielectric block is now rotated, with respect to the original layout, by an angle \(\varphi\)
\[
\begin{pmatrix}
\tilde{y} \\
\tilde{z}
\end{pmatrix} = \begin{pmatrix}
\cos\varphi & -\sin\varphi \\
\sin\varphi & \cos\varphi
\end{pmatrix} \begin{pmatrix}
y_s \\
z_s
\end{pmatrix}.
\]

The transmissivity through a triangular air gap can be immediately obtained from Equation (11), by substituting the first transmitted wave amplitude and the loop factor, respectively, by
\[
t^{(s,p)}[q_{\tilde{z}}, p_{\tilde{z}}, 0]r^{(s,p)}[p_{\tilde{z}}, q_{\tilde{z}}, \tilde{L}] \text{ and } \]
\[
r^{(s,p)}[p_{\tilde{z}}, q_{\tilde{z}}, \tilde{L}]t^{(s,p)}[-p_{\tilde{z}}, -q_{\tilde{z}}, 0],
\]
with
\[
\begin{pmatrix}
p_{\tilde{z}} \\
p_{\tilde{z}}
\end{pmatrix} = \begin{pmatrix}
\cos\varphi & -\sin\varphi \\
\sin\varphi & \cos\varphi
\end{pmatrix} \begin{pmatrix}
p_z \\
p_z
\end{pmatrix} \text{ and }
\]
\[
\begin{pmatrix}
q_{\tilde{z}} \\
q_{\tilde{z}}
\end{pmatrix} = \begin{pmatrix}
p_{\tilde{z}}, (n^2k_z^2 - q_{\tilde{z}}^2)^{1/2}
\end{pmatrix}.
\]

We then find
\[
T^{(s,p)}_{\Delta} = \left[\frac{i^{(s,p)}[q_{\tilde{z}}, p_{\tilde{z}}, 0]i^{(s,p)}[p_{\tilde{z}}, q_{\tilde{z}}, \tilde{L}]}{1 - r^{(s,p)}[p_{\tilde{z}}, q_{\tilde{z}}, \tilde{L}]r^{(s,p)}[-p_{\tilde{z}}, -q_{\tilde{z}}, 0]}\right]^{-1}.
\]

Let us first discuss the case of TE waves and rewrite Equation (17) as follows
\[
T^{(s)}_{\Delta} = 4q_{\tilde{z}}p_{\tilde{z}}\exp(-iq_{\tilde{z}}L)\left[(q_{\tilde{z}} + p_{\tilde{z}})/(q_{\tilde{z}} + p_{\tilde{z}})\exp(-ip_{\tilde{z}}L) - (q_{\tilde{z}} - p_{\tilde{z}})/(q_{\tilde{z}} - p_{\tilde{z}})\exp(ip_{\tilde{z}}L)\right]^{-1}
\]
\[
= \exp(-iq_{\tilde{z}}L)\left[\frac{q_{\tilde{z}}p_{\tilde{z}} + p_{\tilde{z}}q_{\tilde{z}}}{2q_{\tilde{z}}p_{\tilde{z}}} \cos(p_{\tilde{z}}L) - i\frac{q_{\tilde{z}}q_{\tilde{z}} + p_{\tilde{z}}p_{\tilde{z}}}{2q_{\tilde{z}}p_{\tilde{z}}} \sin(p_{\tilde{z}}L)\right]^{-1}.
\]

Observing that at the first discontinuity, \(z_s = 0\), the transmissivity is obtained by multiplying \(|\tilde{t}^{(s)}_{\tilde{\Delta}}[q_{\tilde{z}}, p_{\tilde{z}}, 0]|^2\) by the factor \(p_{\tilde{z}}/q_{\tilde{z}}\), whereas at the second discontinuity, \(\tilde{z} = \tilde{L}\), the transmissivity is obtained by multiplying \(|\tilde{t}^{(s,p)}[p_{\tilde{z}}, q_{\tilde{z}}, \tilde{L}]|^2\) by \(q_{\tilde{z}}/p_{\tilde{z}}\), we have for the transmissivity through a triangular air gap
\[
T^{(s)}_{\Delta} = \frac{p_{\tilde{z}}q_{\tilde{z}}}{q_{\tilde{z}}p_{\tilde{z}}} |\tilde{t}^{(s)}_{\tilde{\Delta}}|^2 = \left[\frac{(q_{\tilde{z}}p_{\tilde{z}} + p_{\tilde{z}}q_{\tilde{z}})^2}{4p_{\tilde{z}}q_{\tilde{z}}q_{\tilde{z}}p_{\tilde{z}}} \beta^{(s)}_{\Delta} - i\frac{(q_{\tilde{z}}q_{\tilde{z}} + p_{\tilde{z}}q_{\tilde{z}})^2}{4p_{\tilde{z}}q_{\tilde{z}}q_{\tilde{z}}p_{\tilde{z}}} \sin^2(p_{\tilde{z}}L) \sin^2(p_{\tilde{z}}L)\right]^{-1},
\]
(19)
with
\[
\beta^{(s)}_{\Delta} = 1 + \frac{(q_{\tilde{z}}p_{\tilde{z}} - p_{\tilde{z}}q_{\tilde{z}})^2}{4p_{\tilde{z}}q_{\tilde{z}}p_{\tilde{z}}q_{\tilde{z}}},
\]
and
\[
\alpha^{(s)}_{\Delta} = \frac{(q_{\tilde{z}}^2 - p_{\tilde{z}}^2)(q_{\tilde{z}}^2 - p_{\tilde{z}}^2)}{4p_{\tilde{z}}q_{\tilde{z}}p_{\tilde{z}}q_{\tilde{z}}} = \alpha^{(s)}_{\Delta} \frac{p_{\tilde{z}}q_{\tilde{z}}}{p_{\tilde{z}}q_{\tilde{z}}}.
\]
(20)

For TM waves, we find
\[
T^{(p)}_{\Delta} = \left[\frac{(q_{\tilde{z}}p_{\tilde{z}} + p_{\tilde{z}}q_{\tilde{z}})^2}{4p_{\tilde{z}}q_{\tilde{z}}q_{\tilde{z}}p_{\tilde{z}}} \beta^{(p)}_{\Delta} - i\frac{(q_{\tilde{z}}q_{\tilde{z}} + p_{\tilde{z}}q_{\tilde{z}})^2}{4p_{\tilde{z}}q_{\tilde{z}}q_{\tilde{z}}p_{\tilde{z}}} \sin^2(p_{\tilde{z}}L) \sin^2(p_{\tilde{z}}L)\right]^{-1},
\]
(21)
with

\[ \beta^{(p)} = \beta^{(s)} \text{ and } \alpha^{(p)} = \frac{(q_{z^*}^2/n^2 - n^2 p_{z^*}^2)(q_{z^*}^2/n^2 - n^2 p_{z^*}^2)}{4p_{z^*}q_{z^*}p_{z^*}q_{z^*}}. \]

\[ \alpha^{(p)} = \frac{p_{z^*}q_{z^*}(n^2 + 1)p_{z^*}^2 - n^2 k^2}{p_{z^*}q_{z^*}(n^2 + 1)p_{z^*}^2 - n^2 k^2}. \tag{22} \]

5. Conclusions

The major difficulty in positioning two parallel surfaces sufficiently close to each other to allow resonance phenomena or to frustrate total internal reflection is controlling their distance with accuracy and precision. To overcome this difficulty, a triangular configuration has been suggested [13], see Figure 3. This configuration was first investigated by using spectral lamps as a light source [18] and recently by using a He–Ne laser beam [13].

Using the well-known technique of multiple step analysis [21–23] for rectangular air gaps [14,15], we have proposed a new formula for the transmission through a dielectric/ar/dielectric triangular system,

\[
T^{(s,p)}_{\Delta} = \left[ \beta_{\Delta} + \alpha^{(s,p)}_{\Delta} \right]^{-1} \sin^2 \left[ \frac{k}{p_{z^*}} \left( \cos \varphi (1 - n^2 \sin^2 \theta_s)^{1/2} + n \sin \varphi \sin \theta_s \right) \frac{h}{L} \right]. \tag{23} \]

These formulas have to be compared with the formulas used in literature and given in Equation (3),

\[
T^{(s,p)}_{\square} = \left[ 1 + \alpha^{(s,p)}_{\square} \sin^2 \left( \frac{k (1 - n^2 \sin^2 \theta_s)^{1/2}}{p_{z^*}} \right) \frac{h}{L_s} \right]^{-1}. \tag{24} \]

Figure 3. The double prism configuration recently used to analyze frustrated total internal reflection. By changing the incidence point of the light, we can study the propagation through air gaps of different thickness and, for resonance phenomena, test our theoretical predictions. (The color version of this figure is included in the online version of the journal.)

Figure 4. Expected resonances for the standard, \( T_{\square} \), and new, \( T_{\Delta} \), formulas for TE waves.
As observed in the introduction, the condition \( \varphi \ll 1 \) is a necessary condition to guarantee, in the case of diffusion, coherence and consequently resonance phenomena and, in the case of tunneling, frustrated total internal reflection, see Figure 3(a). In this case, \( p_\varphi \approx p_{\varphi_e} + \varphi p_{\varphi_e} \).

In looking for significant differences between the standard formula and the new formula proposed in this paper, we have to amplify the \( \varphi \)-term in \( p_\varphi \). This can be done by increasing \( h \) in the sine argument. To estimate for which values of \( h \) the resonances obtained from the approximated formula given in Equation (24) differ from the resonances calculated from the new formula given in Equation (23), let us explicitly show the resonance conditions for each case:

\[
\begin{align*}
\frac{2\pi}{\lambda} (1 - n^2 \sin^2 \theta_e)^{1/2} h_{\varphi} & \approx m \pi, \\
\frac{2\pi}{\lambda} (1 - n^2 \sin^2 \theta_e)^{1/2} h_{\varphi_e} & \approx m \pi \\
& \times \left( 1 - \varphi \frac{n \sin \theta_e}{(1 - n^2 \sin^2 \theta_e)^{1/2}} \right).
\end{align*}
\]

(25)

Figure 6. Comparison between the standard \( T_\square \) and new, \( T_\triangle \), formulas for TE waves in the case of incidence angles near to the critical angle \( \theta_e = \pi/4 \).

It is clear that the maximum shift between the resonances is obtained for

\[
\frac{m \varphi}{(1 - n^2 \sin^2 \theta_e)^{1/2}} = \frac{1}{2}.
\]

This implies, \( m \approx 1/\varphi \) and consequently an incident point on the first interface, \( h \), of the order of \( \lambda/\varphi \). Another important quantity to be estimated is the distance between two successive resonances, \( \Delta h \approx \lambda/\varphi \). For wavelengths of the order of \( 10^{-7} \) m, we find

<table>
<thead>
<tr>
<th>( \varphi )</th>
<th>( h[\text{m}] )</th>
<th>( \Delta h[\text{mm}] )</th>
</tr>
</thead>
<tbody>
<tr>
<td>10^{-2}</td>
<td>10^{-3}</td>
<td>10^{-2}</td>
</tr>
<tr>
<td>10^{-3}</td>
<td>10^{-1}</td>
<td>10^{-1}</td>
</tr>
<tr>
<td>10^{-4}</td>
<td>10</td>
<td>1</td>
</tr>
</tbody>
</table>

In Figure 4 (TE waves) and Figure 5 (TM waves), we plot the transmission probabilities, (23) and (24), for \( \varphi = 0.001 \) \( (n = 2^{1/2}, \lambda = 2\pi 10^{-7} \text{m}) \) in the case of diffusion, \( \theta_e = \pi/6 \). Deviations are evident for incidence points of light of order of 10 cm.
For incidence angles very close to the critical angle
\[ \theta_\star = \theta_\star^c - \delta^2 ( \delta \ll 1 ), \]
we find
\[
T_\Delta[\theta_\star^c - \delta^2] = \left[ 1 + \frac{\gamma_\Delta^2 - 1}{4\gamma_\Delta} + \gamma_\Delta(n^2 - 1)(\pi/\lambda)^2(\hbar/\lambda)^2 \right]^{-1}
\]
s-waves,
\[
\approx \left[ 1 + \frac{\gamma_\Delta^2 - 1}{4\gamma_\Delta} + \gamma_\Delta(n^2 - 1)(\pi/n)^2(\hbar/\lambda)^2 \right]^{-1}
p-waves,
\]
where
\[
\gamma_\Delta = 1 + \frac{\varphi}{[2(n^2 - 1)\pi/\delta]^{1/2}}.
\]

In Figure 6 (TE waves) and Figure 7 (TM waves), we compare the new results with formula (2). Deviations are evident for \( \delta \leq \varphi \). Nevertheless, the localization, \( d \), of the incoming beam gives a constraint on this parameter,
\[ k\delta^2 \approx d. \]

For a beam waist of the order of mm and a wavelength \( \lambda = 2\pi \times 10^{-7} \) m, we find
\[ \delta \approx 10^{-2} \]
and no difference can be seen between the two formulas. This suggests that differences between the standard and the new formulas can be only seen for light diffusion and not for tunneling of light. Experiments can be prepared by an appropriate choice of \( \varphi \). Observe that by increasing the angle \( \varphi \), we anticipate the shift between the resonances (for example \( \varphi = 0.01 \Rightarrow \hbar \approx \text{mm} \)) but we drastically increase the number of resonances \( 10^2 \) in a few mm. The choice of the best \( \varphi \) essentially depends on the laser wavelength.
