INTRODUCTION

The objective of this paper is to report applications of the approach of Stöhr-Voloch to the Hasse-Weil bound [99], to the investigation of the uniqueness of certain optimal curves,
as well as to the search of upper bounds for the second largest size that a complete plane arc (in a projective plane of odd order) can have.

Let $\mathcal{X}$ be a (projective, geometrically irreducible, non-singular algebraic) curve of genus $g$ defined over a finite field $\mathbb{F}_q$ of $q$ elements. Weil [108] showed that

\[(\ast) \quad |\#\mathcal{X}(\mathbb{F}_q) - (q + 1)| \leq 2\sqrt{q}g,
\]

being this bound sharp as Example 4.4 here shows. Goppa [37] constructed linear codes from curves defined over $\mathbb{F}_q$. These codes were used by Tsfasman, Vladut and Zink [105] to show that the Gilbert-Varshamov bound can be improved whenever $q$ is a square and $q \geq 49$. This was an unexpected result for coding theorist.

The length and the minimum distance of Goppa codes are related with the number of $\mathbb{F}_q$-rational points in the underlying curve. Then Goppa’s construction provided motivation and in fact reawakened the interest in the study of rational points of curves which, despite of this motivation, is an interesting mathematical problem by its own.

Serre [93] noticed that ($\ast$) can be improved by replacing $2\sqrt{q}$ by $[2\sqrt{q}]$. A refined version of Ihara [58] shows that

\[g > \frac{q^2 - q}{2\sqrt{q}^2 + 2\sqrt{q} - 2q} \quad \Rightarrow \quad \#\mathcal{X}(\mathbb{F}_q) < q + 1 + [2\sqrt{q}]g,
\]

and in this case Serre [93], [95] upper bounded $\#\mathcal{X}(\mathbb{F}_q)$ via explicit formulae.

A geometric point of view to bound $\#\mathcal{X}(\mathbb{F}_q)$ was introduced by Stöhr and Voloch [99]: Suppose that $\mathcal{X}$ admits a base-point-free linear series $g_r^d$ defined over $\mathbb{F}_q$; then

\[\#\mathcal{X}(\mathbb{F}_q) \leq \sum_{i=0}^{r-1} \nu_i(2g - 2) + (q + r)d,
\]

where $\nu_0, \ldots, \nu_{r-1}$ are certain $\mathbb{F}_q$-invariants associated to $g_r^d$ (see Theorem 3.13 here). By an appropriate choice of $g_r^d$ this result implies ($\ast$) [99, Cor. 2.14], and in several cases one obtains improvements on ($\ast$). We write an exposition of Stöhr-Voloch’s approach in Sect. 3.

For the sake of completeness we include an expository account on Weierstrass point theory of linear series on curves: Sects. 1, 2.

Next we discuss two applications of [99] studied here. The first one is concerning the uniqueness of certain optimal curves. The most well known example of a $\mathbb{F}_q$-maximal curve is the Hermitian curve (Example 4.4 here) whose genus is $\sqrt{q}(\sqrt{q} - 1)/2$; i.e., the biggest one that a $\mathbb{F}_q$-maximal curve can have according to the aforementioned Ihara’s result. Rück and Stichtenoth [87] showed that this property characterize Hermitian curves up to $\mathbb{F}_q$-isomorphic. In Sect. 4.1 we equip the curve $\mathcal{X}$ with a linear series $\mathcal{D}_\mathcal{X}$ obtained from its Zeta Function provided that $\mathcal{X}(\mathbb{F}_q) \neq \emptyset$. It turns out that $\mathcal{D}_\mathcal{X} = |(\sqrt{q} + 1)P_0|$, $P_0 \in \mathcal{X}(\mathbb{F}_q)$, whenever $\mathcal{X}$ is $\mathbb{F}_q$-maximal. Then applying [99] to $\mathcal{D}_\mathcal{X}$ we prove a stronger version of Rück-Stichtenoth’s result; see Theorem 4.24 here. Further properties of $\mathbb{F}_q$-maximal were proved via an interplay of Stöhr-Voloch’s paper [99], and results on linear
series such as Castelnuovo’s genus bound and Halphen’s theorem applied to $D_X$; see [24], [26],[67],[68]. A characterization result is also proved for the Suzuki curve (Theorem 4.27), which in fact is optimal with genus $q_0(q - 1)$ and $(q^2 + 1)$ $F_q$-rational points.

The second application of [99] studied here is the bounding of the size $k$ of a complete plane arc $K$ in $\mathbb{P}^2(F_q)$ which indeed is a basic problem in Finite Geometry. What it makes this possible is the fact that associated to $K$ there is a (possible singular) plane curve $C$. A fundamental result of B. Segre [90] (see Theorem 5.2 here for the odd case) allows then to upper bound $k$ via [99] applied to certain linear series defined on the non-singular model of an irreducible component of $C$. Details of the following discussion can be seen in Sect. 5. The largest $k$ is already well known and so the problem is concerning the second largest size $m'_2(2, q)$. Let $q$ be a square. If $q$ is even, then $m'(2, q) = q - \sqrt{q} + 1$ and a similar result is expected for $q$ odd, $q \geq 49$. Let $q$ be odd. Applying $(\ast)$ B. Segre showed that $m'(2, q) \leq q - \sqrt{q}/4 + 7/4$. One obtains the same bound by using [99]; see Proposition 5.11 here. If in addition, for $q$ large, one takes into consideration a bound for the number of $F_q$-rational of plane curves due to Hirschfeld and Korchmáros [68] (see Theorem 5.24 here) one finds the currently best upper bound for $m'(2, q)$, namely

$$m'(2, q) \leq q - \frac{\sqrt{q}}{2} + \frac{5}{2}.$$ 

So far, for $\sqrt{q} \notin \mathbb{N}$, the best upper bound for $m'(2, q)$ is due to Voloch [106], [107]; see Lemmas 5.17, 5.19 here.

This paper is an outgrowth and a considerable expanded of lectures given at the University of Essen in April 1997 and the University of Perugia in February 1998.

**Convention.** The word curve will mean a projective, irreducible, non-singular algebraic curve.

1. **Linear series on curves**

The purpose of this section is to summarize relevant material regarding linear series on curves. Standard references are Arbarello-Cornalba-Griffiths-Harris [3], Griffiths [39], Griffiths-Harris [40], Hartshorne [45], Namba [79], Seidenberg [91], Stichtenoth [96].

Let $X$ be a curve over an algebraically closed field $F$; set $P := P^r(F)$.

1.1. Terminology and notation. We start by fixing some terminology and notation.

1.1.1. We denote by $\text{Div}(X)$ the group of divisors on $X$; i.e., the $\mathbb{Z}$-free abelian group generated by the points of $X$. Let $D = \sum n_P P \in \text{Div}(X)$. The multiplicity of $D$ at $P$ is $v_P(D) := n_P$. The divisor $D$ is called effective (notation: $D \geq 0$) if $v_P(D) \geq 0$ for each $P$. For $D, E \in \text{Div}(X)$, we write $D \geq E$ if $D - E \geq 0$. The degree of $D$ is the number $\deg(D) := \sum v_P(D)$, and the support of $D$ is the set $\text{Supp}(D) := \{ P \in X : v_P(D) \neq 0 \}$.
1.1.2. Let $\mathbf{F}(\mathcal{X})$ denote the field of rational functions on $\mathcal{X}$. Associated to $f \in \mathbf{F}(\mathcal{X})^* := \mathbf{F}(\mathcal{X}) \setminus \{0\}$ we have the divisor

$$\text{div}(f) := \sum v_P(f)P,$$

where $v_P$ stands for the valuation at $P \in \mathcal{X}$. Recall that $v_P$ satisfies: $v_P(0) := +\infty$, $v_P(f + g) \geq \min(v_P(f), v_P(g))$, and $v_P(fg) = v_P(f) + v_P(g)$ for $f, g \in \mathbf{F}(\mathcal{X})$.

For $f \in \mathbf{F}^* := \mathbf{F}\setminus\{0\}$, $\text{div}(f) = 0$ and for $f \in \mathbf{F}(\mathcal{X})\setminus\mathbf{F}$, $\text{div}(f) = \text{div}_0(f) - \text{div}_\infty(f)$, where $\text{div}_0(f) := \sum_{v_P(f)>0} v_P(f)P$ and $\text{div}_\infty(f) := \sum_{v_P(f)<0} (-v_P(f))P$ are respectively the zero and the polar divisor of $f$. Moreover, $\deg(\text{div}(f)) = 0$ and $\text{div}(f) = \text{div}(f) + \text{div}(g)$.

Associated to $D \in \text{Div}(\mathcal{X})$ we have the $\mathbf{F}$-linear space

$$L(D) := \{f \in \mathbf{F}(\mathcal{X})^* : D + \text{div}(f) \geq 0\} \cup \{0\},$$

where $\ell(D) := \dim_\mathbf{F} L(D) \leq \deg(D) + 1$. For $D, E \in \text{Div}(\mathcal{X})$ such that $L(D) \subseteq L(E)$, we have

$$\ell(E) - \ell(D) \leq \deg(E) - \deg(D).$$

The Riemann-Roch theorem computes $\ell(D)$: If $C$ is a canonical divisor on $\mathcal{X}$ and $g$ is the genus of $\mathcal{X}$, then

$$\ell(D) = \deg(D) + 1 - g + \ell(C - D).$$

In particular, $C$ is characterized by the properties: $\deg(C) = 2g - 2$ and $\ell(C) \geq g$.

A local parameter at $P \in \mathcal{X}$ is a rational function $t \in \mathbf{F}(\mathcal{X})$ such that $v_P(t) = 1$. Associated to $f \in \mathbf{F}(\mathcal{X})^*$ we have its local expansion at $P$, $\sum_{i=v_P(f)}^\infty a_it^i$, where $a_{v_P(f)} \neq 0$.

Let $f \in \mathbf{F}(\mathcal{X})$ be a separating variable of $\mathbf{F}(\mathcal{X})|\mathbf{F}$; i.e., let the field extension $\mathbf{F}(\mathcal{X})|\mathbf{F}(f)$ be separable. Then we have the divisor of the differential of $f$, namely $\text{div}(df)$ where $v_P(\text{div}(df))$ equals the minimum integer $i$ such that $ia_i \neq 0$. It holds that $\deg(\text{div}(df)) = 2g - 2$.

1.1.3. Two divisors $D, E \in \text{Div}(\mathcal{X})$ are called linearly equivalent (notation: $D \sim E$) if there exists $f \in \mathbf{F}(\mathcal{X})^*$ such that $D = E + \text{div}(f)$. In this case, $\deg(D) = \deg(E)$ and $L(D)$ is $\mathbf{F}$-isomorphic to $L(E)$ via the map $g \mapsto fg$. For $E \in \text{Div}(\mathcal{X})$, let

$$|E| := \{D \in \text{Div}(\mathcal{X}) : D \geq 0, \ D \sim E\};$$

i.e.,

$$|E| = \{E + \text{div}(f) : f \in L(E) \setminus \{0\}\}.$$

Since, for $f, g \in \mathbf{F}(\mathcal{X})^*$, $\text{div}(f) = \text{div}(g)$ if and only if there exists $a \in \mathbf{F}^*$ such that $f = ag$, the set $|E|$ is equipped with a structure of projective space by means of the map $E + \text{div}(f) \in |E| \mapsto [f] \in \mathbf{P}(L(E))$; notation: $|E| \cong \mathbf{P}(L(E))$.

A linear series $\mathcal{D}$ on $\mathcal{X}$ is a subset of some $|E|$, of type

$$\{E + \text{div}(f) : f \in \mathcal{D}' \setminus \{0\}\},$$

with $\mathcal{D}'$ being a $\mathbf{F}$-linear subspace of $L(E)$. The numbers $d = \deg(\mathcal{D}) := \deg(E)$ and $r = \dim(\mathcal{D}) := \dim_\mathbf{F}(\mathcal{D}') - 1$ are called respectively the degree and the (projective) dimension.
of \( D \). We say that \( D \) is a \( g_d^* \) on \( X \). \( D \) is called complete if \( D = |E| \). Observe that, under the identification \( |E| \cong \text{P}(L(E)) \), \( D \) corresponds to \( \text{P}(D') \); notation: \( D \cong \text{P}(D') \subseteq |E| \).

A linear series \( D_1 \cong \text{P}(D'_1) \subseteq |E_1| \) will be called a subspace of \( D \cong \text{P}(D') \subseteq |E| \) if \( L(E_1) \subseteq L(E) \) and \( D'_1 \subseteq D' \).

1.1.4. Let \( P \in X \) and \( f \in \text{F}(X) \) regular at \( P \); i.e., \( v_P(f) \geq 0 \). Then there exists a unique \( a_f \in \text{F} \) such that \( v_P(f - a_f) > 0 \). We set \( f(P) := a_f. \) For \( f, g \in \text{F}(X) \) regular at \( P \), \((f + g)(P) = f(P) + g(P) \) and \((fg)(P) = f(P)g(P) \). A point of the \( r \)-projective space \( \text{P}^r \) will be denoted by \((a_0 : \cdots : a_r)\).

Let \( \phi : X \to \text{P}^r \) be a morphism; i.e., let \( f_0, \ldots, f_r \in \text{F}(X) \), not all zero, such that

\[
\phi(P) = ((t^{e_P} f_0)(P): \ldots: (t^{e_P} f_r(P)),
\]

where \( t \) is a local parameter at \( P \), and

\[
e_P := -\min\{v_P(f_0), \ldots, v_P(f_r)\}.
\]

Observe that each \( t^{e_P} f_i \) is regular at \( P \). The rational functions \( f_0, \ldots, f_r \) are called (homogeneous) coordinates of \( \phi \). We set

\[
\phi = (f_0 : \ldots : f_r).
\]

The coordinates \( f_0, \ldots, f_r \) are uniquely determined by \( \phi \) up to a factor in \( \text{F}(X)^* \); so \( \phi \) corresponds to a point of \( \text{P}^r(\text{F}(X)) \). If \( \phi \) is non-constant, the image \( \phi(X) \) is a (possible singular) algebraic curve in \( \text{P}^r \) whose function field is \( \text{F}(\phi(X)) = \text{F}(f_0/f_i, \ldots, f_r/f_i) \) for some \( f_i \neq 0 \). The curve \( X \) can be thought as a parametrized curve in \( \text{P}^r \), or \( \phi(X) \) as being a concrete manifestation of \( X \) in \( \text{P}^r \). For \( Q \in \phi(X) \), the points of the fiber \( \phi^{-1}(Q) \) will be called the branches of \( \phi(X) \) centered at \( Q \). The degree of \( \phi \) is \( \text{deg}(\phi) := [\text{F}(X) : \text{F}(\phi(X))] \).

**Example 1.1.** Each rational function \( f \in \text{F}(X) \) can be seen as a morphism \( f : X \to \text{P}^1 = \text{F} \cup \{\infty\} \), such that \( P \mapsto f(P) \) if \( P \not\in \text{div}\_\infty(f) \); \( P \mapsto \infty \) otherwise. If \( f \not\in \text{F} \), we have \( d := \text{deg}(f) = [\text{F}(X) : \text{F}(f)] = \text{deg}(\text{div}\_\infty(f)) \). Moreover, if \( \text{F}(X)[f] \) is separable, the genus \( g \) of \( X \) can be computed via the so-called Riemann-Hurwitz formula:

\[
2g - 2 = d(-2) + \text{deg}(R_f),
\]

where \( R_f = \text{div}(df) + 2\text{div}\_\infty(f) \) is the ramification divisor of \( f \). If \( \text{char}(\text{F}) \) does not divide the ramification index \( e_P \) of \( f \) over \( P \), then \( v_P(R_f) = e_P - 1 \) otherwise \( v_P(R_f) > e_P - 1 \).

We have the product formula

\[
\sum_{P \in f^{-1}(f(P))} e_P = d.
\]

Let \( \phi \) be non-constant. For all but finitely many \( Q \in \phi(X) \), \( \#\phi^{-1}(Q) \) equals the separable degree of \( \text{F}(\phi(X))[\text{F}(\phi(X))] \). \( \phi \) is called birational (resp. embedding) if \( \text{deg}(\phi) = 1 \) (resp. \( X \) is \( \text{F} \)-isomorphic to \( \phi(X) \)); in both cases, \( X \) is a (the) non-singular model of \( \phi(X) \).

Let \( H \) be a hyperplane in \( \text{P}^r \) such that \( \phi(X) \not\subseteq H \). Then \( \#\phi(X) \cap H \) is finite. To each \( P \in X \) one associates a number \( I_P(H) = I(\phi(X), H; \phi(P)) \), called the intersection
multiplicity of $\phi(X)$ and $H$ at $\phi(P)$, in such a way that $I_P = 0 \Leftrightarrow \phi(P) \not\in \phi(X) \cap H$ and that $\sum I_P(H)$ is independent of $H$; i.e., if $H'$ is another hyperplane in $\mathbb{P}^r$ such that $\phi(X) \not\subseteq H'$, then $\sum I_P(H) = \sum I_P(H')$. This number is called the degree $\deg(\phi(X))$ of $\phi(X)$. If $\phi(X) \subseteq \mathbb{P}^2$, the degree of $\phi(X)$ equals the degree of the polynomial that defines $\phi(X)$ (see [45, p. 53]). A morphism $\phi : X \to \mathbb{P}^r$ is called non-degenerate if $\phi(X) \not\subseteq H$ for each hyperplane $H$ in $\mathbb{P}^r$. A curve $X \subseteq \mathbb{P}^r$ is called non-degenerate if the inclusion morphism $X \hookrightarrow \mathbb{P}^r$ is so.

Lemma 1.2. A morphism $\phi = (f_0 : \ldots : f_r) : X \to \mathbb{P}^r$ is non-degenerate if and only if $f_0, \ldots, f_r$ are $\mathbb{F}$-linearly independent.

Proof. There exists a hyperplane $H$ in $\mathbb{P}^r$ such that $\phi(X) \subseteq H$ if and only if there exist $a_0, \ldots, a_r \in \mathbb{F}$, not all zero, such that $\sum_i a_i f_i(P) = 0$ for all but finitely many $P \in X$. The last condition is equivalent to $\sum_i a_i f_i = 0$, as a non-zero rational function has only finitely many zeros (cf. Sect. 1.1.2); now the result follows.

For $V \subseteq \mathbb{F}(X)$, $\langle V \rangle$ stands for the $\mathbb{F}$-vector space in $\mathbb{F}(X)$ generated by $V$.

1.2. Morphisms from linear series; Castelnuovo’s genus bound. Let $\mathcal{D}$ be a $r$-dimensional linear series on $X$, say $\mathcal{D} \cong \mathbb{P}(\mathcal{D}') \subseteq |E|$. The following subsets will provide information on the geometry of $X$.

Definition. For $P \in X$ and $i \in \mathbb{N}_0$,

$$D_i(P) := \{ D \in \mathcal{D} : D \geq iP \}.$$ 

Clearly $D_i(P) \supseteq D_{i+1}(P)$ and $D_i(P) = \emptyset$ if $i > d$.  

Lemma 1.3. (1) $D_i(P)$ is a linear series;  
(2) $D_i(P)$ is a subspace of $D$;  
(3) $\dim(D_i(P)) \leq \dim(D_{i+1}(P)) + 1$.

Proof. Set $D_i := D_i(P)$ and let $f \in \mathcal{D}' \setminus \{0\}$. Then $E + \text{div}(f) \in D_i$ if and only if $v_P(E) + v_P(f) \geq i$; i.e., $D_i \cong \mathbb{P}(\mathcal{D}_i')$, where

$$\mathcal{D}_i' := \mathcal{D}' \cap L(E - iP).$$

This shows parts (1) and (2). Now $\mathcal{D}_i'/\mathcal{D}_{i+1}'$ is $\mathbb{F}$-isomorphic to a $\mathbb{F}$-subspace of $\mathcal{L} := L(E - iP)/L(E - (i + 1)P)$. Since $\dim_F \mathcal{L} \leq 1$ (see Sect. 1.1.2), part (3) follows.

Definition. The multiplicity of $\mathcal{D}$ at $P \in X$ is defined by

$$b(P) := \min \{ v_P(D) : D \in \mathcal{D} \}.$$
We have \( b(P) > 0 \) if and only if \( P \in \text{Supp}(D) \) for all \( D \in \mathcal{D} \); so \( b(P) \neq 0 \) for finitely many \( P \in \mathcal{X} \). Consequently, we can define the effective divisor \( B = B^D \) on \( \mathcal{X} \) by setting

\[
v_P(B) := b(P).
\]

**Definition.** The divisor \( B \) is called the base locus of \( \mathcal{D} \). A point \( P \in \text{Supp}(B) \) is called a base point of \( \mathcal{D} \). If \( B = 0 \), \( \mathcal{D} \) is called base-point-free.

Thus \( \mathcal{D} \) is base-point-free if and only if for each \( P \in \mathcal{X} \) there exists \( f \in \mathcal{D}' \setminus \{0\} \) such that \( v_P(E + \text{div}(f)) = 0 \). Now, since \( D \geq B \) for each \( D \in \mathcal{D}, \mathcal{D}' \subseteq L(E - B) \) and

\[
\mathcal{D}^B := \{D - B : D \in \mathcal{D}\} \subseteq |E - B|
\]

is a subspace of \( \mathcal{D} \) such that \( \mathcal{D}^B \cong \mathbb{P}(\mathcal{D}') \subseteq |E - B| \). We have \( B^{\mathcal{D}^B} = 0 \); i.e., \( \mathcal{D}^B \) is a \( g^r_{d - \deg(B)} \) base-point-free on \( \mathcal{X} \).

**Lemma 1.4.** Let \( \mathcal{D} \cong \mathbb{P}(\mathcal{D}') \subseteq |E| \) be a linear series, where \( \mathcal{D}' = \langle f_0, \ldots, f_s \rangle \). Then \( E \) is determined by \( \mathcal{D} \); i.e.,

\[
v_P(E) = b(P) - \min\{v_P(f_0), \ldots, v_P(f_s)\}.
\]

**Proof.** Since \( \mathcal{D}' \subseteq L(E - B), v_P(E) - b(P) + v_P(f_i) \geq 0 \) for each \( i \) and each \( P \) so that \( v_P(E) \geq b(P) - \min\{v_P(f_0), \ldots, v_P(f_s)\} \). On other hand, as \( \mathcal{D}^B \) is base-point-free, for each \( P \) there exists \( (a_0 : \ldots : a_s) \in \mathbb{P}^s(\mathbb{F}) \) such that \( v_P(E - B + \text{div}(\sum a_if_i)) = 0 \); now the result follows.

Next we associate a morphism to \( \mathcal{D} \). For \( P \in \mathcal{X} \) we have \( \mathcal{D} = \mathcal{D}_{b(P)}(P) \supsetneq \mathcal{D}_{b(P)+1}(P) \), so that \( \dim(\mathcal{D}_{b(P)+1}) = \dim(\mathcal{D}) - 1 \) by Lemma 1.3. Thus we have the following map

\[
\phi_{\mathcal{D}} : \mathcal{X} \to \mathcal{D}^* \cong \mathbb{P}(\mathcal{D}')^*, \quad P \mapsto \mathcal{D}_{b(P)+1}.
\]

Homogeneous coordinates of \( \phi_{\mathcal{D}} \) are given as follows. Let \( \{f_0, \ldots, f_r\} \) be a \( \mathbb{F} \)-base of \( \mathcal{D}' \), \( t \) a local parameter at \( P \), and \( f \in \mathcal{D}' \setminus \{0\} \). Then \( v_P(t^{v_p(E) - b(P)f}) \geq 0 \) and

\[
E + \text{div}(f) \in \mathcal{D}_{b(P)+1} \iff v_P(t^{v_p(E) - b(P)f}) \geq 1 \iff (t^{v_p(E) - b(P)f})(P) = 0.
\]

Since \( f = \sum_i a_if_i \) with \( (a_0 : \ldots : a_r) \in \mathbb{P}^r \), we have

\[
\mathcal{D}_{b(P)+1} \cong \{ (a_0 : \ldots : a_r) \in \mathbb{P}^r : \sum_{i=0}^r (t^{v_p(E) - b(P)f_i})(P)a_i = 0 \} \subseteq \mathbb{P}^r
\]

\[
\cong \{ (t^{v_p(E) - b(P)f_0})(P) : \ldots : (t^{v_p(E) - b(P)f_r})(P) \} \subseteq \mathbb{P}^r.
\]

Hence from Lemma 1.4 the morphism \( \phi_{f_0, \ldots, f_r} := (f_0 : \ldots : f_r) \) gives a coordinate description of \( \phi_{\mathcal{D}} \), and it will be referred as a morphism associated to \( \mathcal{D} \). If \( \phi_{g_0, \ldots, g_r} \) is another morphism associated to \( \mathcal{D} \), then \( \phi_{g_0, \ldots, g_r} = T \circ \phi_{f_0, \ldots, f_r} \), with \( T \in \text{Aut}(\mathbb{P}^r(\mathbb{F})) \); i.e., a morphism associated to \( \mathcal{D} \) is uniquely determinated by \( \mathcal{D} \), up to projective equivalence. Observe that \( \phi_{\mathcal{D}} \) and \( \phi_{\mathcal{D}^B} \) have the same coordinate description. We summarize the above discussion as follows.
Lemma 1.5. Let $D \cong \mathbb{P}(D')$ be a $r$-dimensional linear series on $X$. Each $F$-base $f_0, \ldots, f_r$ of $D'$ defines a non-degenerate morphism $\phi_{f_0, \ldots, f_r} = (f_0 : \ldots : f_r) : X \to \mathbb{P}^r$. If $g_0, \ldots, g_r$ is another $F$-base of $D'$, then there exists $T \in \text{Aut}(\mathbb{P}^r)$ such that $\phi_{g_0, \ldots, g_r} = T \circ \phi_{f_0, \ldots, f_r}$.

At this point we recall Castelnuovo’s genus bound. Let $g$ be the genus of $X$.

Definition. A linear series $D$ is called simple if a (any) morphism associated to $D$ is birational.

Let $D$ be a simple $g^r_d$, $r \geq 2$, on $X$. Let $d' := d - \deg(B^D)$, and let $\epsilon$ be the unique integer with $0 \leq \epsilon \leq r - 2$ and $d' - 1 \equiv \epsilon \pmod{(r - 1)}$. Define Castelnuovo’s number $c_0(d', r)$ by

$$c_0(d', r) = \frac{d' - 1 - \epsilon}{2(r - 1)} (d' - r + \epsilon).$$

Lemma 1.6. (Castelnuovo’s genus bound for curves in projective spaces, [10], [3, p. 116], [45, IV, Thm. 6.4], [86, Cor. 2.8])

$$g \leq c_0(d', r).$$

Remark 1.7.

$$c_0(d', r) \leq \begin{cases} 
(d' - 1 - (r - 1)/2)^2 / 2(r - 1) & \text{for } r \text{ odd,} \\
(d' - 1 - (r - 1)/2)^2 - 1/4) / 2(r - 1) & \text{for } r \text{ even.}
\end{cases}$$

Remark 1.8. Any curve $X$ of genus $g$ admits a simple $g^2_d$ (i.e., a birational plane model) such that

$$g = d(d - 1)/2 - \sum_P \delta_P,$$

where the $\delta_P$’s are the $\delta$-invariants of the plane curve $\phi(X)$ with $\phi$ being a morphism associated to $g^2_d$. We have that $\delta_P > 0$ if and only if $\phi(X)$ is singular at $P$. A nice method to compute $\delta_P$ was recently noticed by Beelen and Pellikaan [4].

1.3. Linear series from morphisms. Let $\phi = (f_0 : \ldots : f_r) : X \to \mathbb{P}^r$ be a morphism on $X$. In Sect. 1.1.4 we defined

$$e_P = -\min\{v_P(f_0), \ldots, v_P(f_r)\}, \quad P \in X.$$

Then $e_P \neq 0$ for finitely many $P \in X$, and so we have a divisor $E = E_{f_0, \ldots, f_r}$ defined by

$$v_P(E) := e_P.$$

Observe that $f_i \in L(E)$ for each $i$. Let

$$D' := (f_0, \ldots, f_r) \subseteq L(E).$$
Then we have the following linear series on $\mathcal{X}$

$$\mathcal{D}_{f_0, \ldots, f_r} := \{ E + \text{div}(f) : f \in \mathcal{D}' \setminus \{0\} \} \subseteq |E|,$$

which is base-point-free. Indeed, $v_P(E + \text{div}(f_i)) = 0$ where $i_0$ is defined by $e_P = -v_P(f_{i_0})$. 

In addition, if $\phi_1 = (g_0 : \ldots : g_r) = T \circ \phi$ with $T \in \text{Aut}(P^r)$, then

$$\min\{v_P(g_0), \ldots, v_P(g_r)\} = \min\{v_P(f_0), \ldots, v_P(f_r)\},$$

and hence $\mathcal{D}_{g_0, \ldots, g_r} = \mathcal{D}_{f_0, \ldots, f_r}$. Moreover, if $h \in F(\mathcal{X})^*$, then

$$E_{f_0, \ldots, f_r} = E_{f_0, \ldots, f_r} - \text{div}(h)$$

and so

$$\mathcal{D}_{f_0, \ldots, f_r} = \mathcal{D}_{f_0, \ldots, f_r}.$$

Consequently, the linear series $\mathcal{D}_\phi := \mathcal{D}_{f_0, \ldots, f_r}$ is uniquely determined by $\phi$ and it is invariant under projective equivalence of morphisms. Summarizing we have the following.

**Lemma 1.9.** Associated to a morphism $\phi = (f_0 : \ldots : f_r) : \mathcal{X} \to P^r$, there exists a base-point-free linear series $\mathcal{D}_\phi \subseteq |E|$, where $E$ is defined by

$$v_P(E) := -\min\{v_P(f_0), \ldots, v_P(f_r)\}.$$

If $\phi$ is non-degenerate, then $\dim(\mathcal{D}_\phi) = r$. If $\phi_1 = T \circ \phi, T \in \text{Aut}(P^r)$, then $\mathcal{D}_{\phi_1} = \mathcal{D}_\phi$.

In the remaining part of this subsection, we let $\phi = (f_0 : \ldots : f_r)$ be a non-degenerate morphism on $\mathcal{X}$. Then $\mathcal{D}_\phi$ is given by

$$\mathcal{D}_\phi = \{ E + \text{div} \left( \sum_{i=0}^{r} a_i f_i \right) : (a_0 : \ldots : a_r) \in P^r \},$$

because $\sum_i a_i f_i = 0 \iff a_i = 0$ for each $i$ by Lemma 1.2. Therefore, since the point $(a_0 : \ldots : a_r)$ can be identified with the hyperplane $H$ of equation $\sum_i a_i X_i = 0$,

(1.1) $$\mathcal{D}_\phi = \{ \phi^*(H) : H \text{ hyperplane in } P^r \},$$

where $\phi^*(H) = E + \text{div} \left( \sum_{i=0}^{r} a_i f_i \right)$ is the pull-back of $H$ by $\phi$.

**Lemma 1.10.** We have $\phi^*(H) = (T \circ \phi)^*(T(H))$, where $T \in \text{Aut}(P^r)$ and $H$ is a hyperplane in $P^r$.

**Proof.** The result follows from the facts that $E_{\phi} = E_{T \circ \phi}$ and that $T(H) : \sum_i b_i Y_i = 0$, where $(b_0, \ldots, b_r) = (a_0, \ldots, a_r) A^{-1}, A$ being the matrix defining $T$ and $H : \sum_i a_i X_i = 0$. \hfill $\Box$

**Lemma 1.11.** With the aforementioned notation,

(1) $P \in \text{Supp}(\phi^*(H)) \iff \phi(P) \in H; i.e., \text{Supp}(\phi^*(H)) = \phi^{-1}(\phi(\mathcal{X}) \cap H);$

(2) For $P_1 \in \phi^{-1}(\phi(P))$, $P_1 \in \text{Supp}(\phi^*(H)) \iff \phi^{-1}(\phi(P)) \subseteq \text{Supp}(\phi^*(H));$

(3) $d := \deg(\mathcal{D}) = \deg(\phi) \deg(\phi(\mathcal{X})).$
Proof. Let \( t \) be a local parameter at \( P \in \mathcal{X} \).

(1) The proof follows from the equivalences

\[
P \in \text{Supp}(\phi^*(H)) \iff v_P(\text{div}(\sum_i a_i t^p f_i)) \geq 1 \iff (\sum_i a_i t^p f_i)(P) = 0.
\]

(2) The implication (\( \Leftarrow \)) is trivial. (\( \Rightarrow \)): Let \( P_2 \in \phi^{-1}(\phi(P)) \). Then \( \phi(P_1) = \phi(P_2) \) which belong to \( H \) by part (1). Thus, once again by (1) we conclude that \( P_2 \in \text{Supp}(\phi^*(H)) \).

(3) Let \( H_1 \) be a hyperplane in \( \mathbb{P}^r \) such that \( \phi(\mathcal{X}) \cap H \cap H_1 = \emptyset \). Denote by \( h/h_1 \) the rational function on \( \mathbb{P}^r \), obtained by dividing the equation of \( H \) by the one of \( H_1 \). The function \( h/h_1 \) is regular on \( \mathbb{P}^r \setminus H_1 \) and hence \( \varphi \) is regular on \( \phi^{-1}(\mathbb{P}^r \setminus H_1) \). Moreover, by the election of \( H_1 \), we have that \( v_P(\varphi) \geq 1 \iff \phi(P) \in H \) and therefore from part (1) we conclude that \( v_P(\varphi) \geq 1 \iff P \in \text{Supp}(\phi^*(H)) \). From the definition of \( \varphi \) we even conclude that \( \phi^*(H) = \text{div}_0(\varphi) \).

Now suppose that \( \phi(P) = Q \in \phi(\mathcal{X}) \cap H \) is non-singular; let \( u \) be a local parameter at \( Q \) and set \( i_P := v_P(u) \) (the ramification index at \( P \)). By considering \( h/h_1 \) as a function on \( \mathcal{X} \), we have \( v_P(\phi^*(H)) = v_P(\varphi) = i_P v_Q(h/h_1) \), and by the product formula we also have

\[
\sum_{P \in \phi^*(Q)} v_P(\phi^{-1}(H)) = \text{deg}(\phi) v_Q(h/h_1).
\]

Now take \( H \) such that every point in \( \phi(\mathcal{X}) \cap H \) is non-singular (this is possible because \( \phi(\mathcal{X}) \) has a finite number of singular points and so we can apply Bertini’s theorem). Then from the above equation,

\[
d = \text{deg}(\phi) \sum_{Q \in \phi(\mathcal{X}) \cap H} v_Q(h/h_1).
\]

It turns out that \( v_Q(h/h_1) = I(\phi(\mathcal{X}), H; Q) \) (cf. [45, Ex.6.2]), and the result follows. \qed

From this lemma and its proof we obtain:

**Corollary 1.12.** Let \( \phi : \mathcal{X} \to \mathbb{P}^r \) be a non-degenerate morphism.

1. If \( \phi \) is birational; i.e., \( \text{deg}(\phi) = 1 \), then \( \text{deg}(D_\phi) = \text{deg}(\phi(\mathcal{X})) \).
2. If \( \mathcal{X} \subseteq \mathbb{P}^r \) and \( \phi \) is the inclusion morphism, then

\[
D_\phi = \{ \mathcal{X} \cdot H : H \text{ hyperplane in } \mathbb{P}^r \},
\]

where \( \mathcal{X} \cdot H = \sum_P I(\mathcal{X}, H; P) \) is the intersection divisor of \( \mathcal{X} \) and \( H \).
1.4. Relation between linear series and morphisms. Define the following sets:

- \( \mathcal{L} = \mathcal{L}_r := \{ \mathcal{D}^B : \mathcal{D} \text{ linear series with } \dim(D) = r \} \);
- \( \mathcal{M} = \mathcal{M}_r := \{ \langle \phi \rangle : \phi : \mathcal{X} \to \mathbb{P}^r \text{ non-degenerate morphism} \} \), where \( \langle \phi \rangle := \{ T \circ \phi : T \in \text{Aut}(\mathbb{P}^r) \} \) denotes the projective equivalent class of \( \phi \).

From Sects. 1.2 and 1.3 we have two maps, namely

\[ M = M_r : \mathcal{L} \to \mathcal{M}; \quad \mathcal{D}^B \mapsto \langle \text{coordinate representation of } \phi_{\mathcal{D}^B} \rangle, \]

and

\[ L = L_r : \mathcal{M} \to \mathcal{L}; \quad \langle \phi \rangle \mapsto \mathcal{D}_\phi. \]

We have \( M \circ L = \text{id}_\mathcal{M} \) by definition, and \( L \circ M = \text{id}_\mathcal{L} \) by Lemma 1.4. Therefore,

**Lemma 1.13.** The set of base-point-free linear series of dimension \( r \) is equivalent to the set of projective equivalent class of non-degenerate morphism from \( \mathcal{X} \) to \( \mathbb{P}^r \).

**Remark 1.14.** The fact that \( (L \circ M)(\mathcal{D}^B) = \mathcal{D}^B \) means that

\[ \mathcal{D}^B = \{ \phi^*(H) : H \text{ hyperplane in } \mathbb{P}^r \} \subseteq |E - B|, \]

where \( \phi : \mathcal{X} \to \mathbb{P}^r \) is the non-degenerate morphism determined, up to an automorphism of \( \mathbb{P}^r \), by a base of \( \mathcal{D}' \).

1.5. Hermitian invariants; Weierstrass semigroups I. Let \( \mathcal{D} \) be a \( g^*_d \) on \( \mathcal{X} \), say \( \mathcal{D} \cong \mathbb{P}(\mathcal{D}') \subseteq |E| \), and \( P \in \mathcal{X} \). We continue the study of the linear series \( \mathcal{D}_i(P) \) started in Sect. 1.2. Recall that \( \mathcal{D}_i(P)' = \mathcal{D}' \cap L(E - iP) \) and that \( \mathcal{D}_i(P) \supseteq \mathcal{D}_{i+1}(P) \).

**Definition.** A non-negative integer \( j \) is called a (\( \mathcal{D}, P \))-order (or an Hermitian \( P \)-invariant), if \( \mathcal{D}_j(P) \not\supseteq \mathcal{D}_{j+1}(P) \).

From Lemma 1.3, there exist \( r + 1 \) (\( \mathcal{D}, P \))-orders, say

\[ j_0(P) = j_0^D(P) < \ldots < j_r(P) = j_r^D(P). \]

For \( i = 0, \ldots, r \),

\[ j_i(P) = \min \{ v_p(E) + v_p(f) : f \in \mathcal{D}_{j_i}(P)' \}, \]

and thus \( \mathcal{D}_{j_i}(P) \) is a \( g^*_d^{-i} \) on \( \mathcal{X} \).

**Lemma 1.15.** (Esteves-Homma [21, Lemma 1]) For \( P, Q \in \mathcal{X}, P \neq Q \),

\[ j_i(P) + j_{r-i}(Q) \leq d. \]

**Proof.** Since \( \dim(\mathcal{D}_{j_i}(P)(P) \cap \mathcal{D}_{j_{r-i}}(Q)(Q)) \geq 0 \), there exists \( D \in \mathcal{D}_{j_i}(P)(P) \cap \mathcal{D}_{j_{r-i}}(Q)(Q) \) and the result follows.

This result will be complemented by Corollary 2.14.
Remark 1.16. (i) Since \( j_0(P) \) equals \( b(P) \), \( \mathcal{D} \) is base-point-free if and only if \( j_0(P) = 0 \) for each \( P \in \mathcal{X} \). Moreover, \( j \) is a \((\mathcal{D}, P)\)-order if and only if \( j - b(P) \) is a \((\mathcal{D}^B, P)\)-order.

(ii) \( j_r(P) \leq d \) as \( \mathcal{D}_i(P) = \emptyset \) for \( i > d \).

(iii) Let \( j \in \mathbb{N}_0 \). From Lemma 1.3, the following statements are equivalent:

1. \( j \) is a \((\mathcal{D}, P)\)-order;
2. \( \exists D \in \mathcal{D} \) such that \( v_P(D) = j \);
3. \( \exists f \in \mathcal{D}' \) such that \( v_P(E) + v_P(f) = j \);
4. \( \exists f \in \mathcal{D}' \) such that \( f \in L(E - jP) \setminus L(E - (j + 1)P) \);
5. \( \dim_{\mathbb{F}}(\mathcal{D}'_j(P)) = \dim_{\mathbb{F}}(\mathcal{D}'_{j+1}(P)) + 1 \);
6. \( \dim(\mathcal{D}_j(P)) = \dim(\mathcal{D}_{j+1}(P)) + 1 \).

(iv) Let \( \mathcal{D} = |E| \); i.e., \( \mathcal{D}' = L(E) \), \( C \) a canonical divisor on \( \mathcal{X} \), and \( j \in \mathbb{N}_0 \). From \( \mathcal{D}'_j(P) = L(E - jP) \), the Riemann-Roch theorem, and part(iii)(5) above, the following statements are equivalent:

1'. \( j \) is a \(|E|, P\)-order;
2'. \( \exists f \in L(E) \) such that \( v_P(E) + v_P(f) = j \);
3'. \( \exists f \in L(E - jP) \setminus L(E - (j + 1)P) \);
4'. \( L(C - E + (j + 1)P) = L(C - E + jP) \);
5'. \( \forall f \in L(C - E + (j + 1)P) \) such that \( v_P(C - E) + v_P(f) = -(j + 1) \).

Example 1.17. Let \( g \) be the genus of \( \mathcal{X} \), and \( \mathcal{D} := |E| \) with \( d = \deg(E) \geq 2g \). For \( P \in \mathcal{X} \), we compute some \((\mathcal{D}, P)\)-orders. We have \( j_i(P) = i \) for \( 0 \leq i \leq d - 2g \). Indeed for such an \( i \), \( \deg(C - E + (i + 1)P) < 0 \) and then Remark 1.16(iv'(1)) is trivially satisfied. In particular, \( \mathcal{D} \) is base-point-free.

Example 1.18. We claim that for a given sequence of non-negative integers \( \ell_0 < \ldots < \ell_r \), there exists a curve \( \mathcal{Y} \), a point \( P_0 \in \mathcal{Y} \), and a linear series \( \mathcal{F} \) on \( \mathcal{Y} \) such that the sequence equals the \((\mathcal{F}, P_0)\)-orders. Indeed, let \( \mathcal{Y} := \mathbb{P}^1(\mathbb{F}) \) and \( x \) a transcendental element over \( \mathbb{F} \). Set \( P_\infty := (0 : 1) \), and \( P_\alpha := (1 : a) \) for \( a \in \mathbb{F} \). We assume \( \text{div}(x) = P_0 - P_\infty \), \( v_{P_\alpha}(x - a) = 1 \) for \( a \in \mathbb{F} \). Define

\[
E := \ell_i P_\infty, \quad \text{and} \quad \mathcal{F}' := \langle x^{\ell_0}, \ldots, x^{\ell_r} \rangle \subseteq \mathbb{F}(x) .
\]

Then \( \mathcal{F} := \{E + \text{div}(f) : f \in \mathcal{F}'\} \) is a \( g_{\ell_i} \) on \( \mathcal{Y} \). We have \( E + \text{div}(x^{\ell_i}) = \ell_i P_0 + (\ell_r - \ell_i)P_\infty \) and hence the \((\mathcal{F}, P_0)\)-orders are \( \ell_0, \ldots, \ell_r \). In addition, we have that \( j_0^E(P) = 0 \) for \( P \neq P_0 \); i.e., the base locus of \( \mathcal{F} \) is \( B_{\mathcal{F}} = \ell_0 P_0 \). Moreover, for the morphism associated to \( \mathcal{F} \phi = \langle x^a : \ldots : x^{\ell_r} \rangle \) we have \( E_\phi = \ell_i P_0 - \ell_0 P_0 \). If \( \ell_r = r \), then \( \mathcal{F} \) is complete and base-point-free, and the curve \( \phi(\mathcal{Y}) \) is the so-called rational normal curve in \( \mathbb{P}^r \). Conversely, if \( \mathcal{F} \) is complete, say \( \mathcal{F} = |E_1| \), then \( E_1 = E \) by Lemma 1.4, and so \( \ell = r \).

We will introduce next the so-called Weierstrass semigroup. To begin with we state a definition which is motivated by Remark 1.16(iv)(5').
**Definition.** Let $D \in \text{Div}(\mathcal{X})$ and $\ell \in \mathbb{N}_0$. We say that $\ell$ is a $(D, P)$-gap if does not exist $f \in L(D + \ell P)$ such that $v_P(D) + v_P(f) = -\ell$.

We have that $\ell$ is a $(D, P)$-gap if and only if $\ell - 1$ is a $(|C - D|, P)$-order, where $C$ is a canonical divisor on $\mathcal{X}$. Denote by $K = K_{\mathcal{X}} := |C|$ the canonical linear series on $\mathcal{X}$.

**Definition.** The $(0, P)$-gaps are called the *Weierstrass gaps* at $P$. The *Weierstrass semigroup* at $P$ is the set

$$H(P) := \mathbb{N}_0 \setminus G(P),$$

where

$$G(P) := \{\ell \in \mathbb{Z}^+ : \ell \text{ Weierstrass gap at } P\}.$$

The elements of $H(P)$ are called *Weierstrass non-gaps* at $P$.

**Lemma 1.19.** Let $g$ be the genus of $\mathcal{X}$. Then

1. $\#G(P) = g$ (Weierstrass gap theorem);
2. For $h \in \mathbb{N}_0$, the following statements are equivalent:
   1. $h \in H(P)$;
   2. $\exists f_h \in L(h P)$ such that $v_P(f_h) = -h$;
   3. $\exists f_h \in k(X)$ such that $\text{div}_\infty(f_h) = hP$;
   4. $\ell(h P) = \ell((h - 1)P) + 1$.

**Proof.** Since $\dim(K) = g - 1$ and

$$G(P) = \{j_0^K(P) + 1, \ldots, j_{g - 1}^K(P) + 1\},$$

part (1) follows. Remark 1.16(iv) implies part (2). \qed

We see now that $H(P)$ is indeed a semigroup.

**Corollary 1.20.** The set $H(P)$ is a sub-semigroup of $(\mathbb{N}_0, +)$ such that

$$H(P) \supseteq \{2g, 2g + 1, 2g + 2, \ldots\},$$

where $g$ is the genus of $\mathcal{X}$.

**Proof.** It follows from Lemma 1.19(2.(iii)) and $j_{g - 1}^K(P) \leq \deg(K) = 2g - 2$. \qed

Let $(n_i(P) : i = 0, 1, \ldots)$ denote the strictly increasing sequence that enumerates the Weierstrass semigroup $H(P)$. From Lemma 1.19(2.(iv)), $\ell(n_i(P)P) = i + 1$ and from Corollary 1.20, $n_i(P) = g + i$ for $i \geq g$.

**Remark 1.21.** For $g = 0$, $K = \emptyset$ and hence $H(P) = \mathbb{N}_0$ for any $P \in \mathcal{X}$. If $g = 1$, then $\dim(K) = 0$ and hence $H(P) = \{0, 2, 3, \ldots\}$ for any $P \in \mathcal{X}$. 
Corollary 1.22. If $X$ is a curve of genus $g \geq 1$, then $K$ is base-point-free.

Proof. We have to show that $j_0(P) := j_0^0(P) = 0$ for each $P \in X$. Suppose that $j_0(P_0) \geq 1$ for some $P_0 \in X$. Then $1 \in H(P_0)$ and hence $H(P_0) = N_0$. This implies $g = 0$. □

Example 1.23. We consider complete linear series on $X$ arising from Weierstrass non-gaps which will be useful for applications to optimal curves. Let $P \in X$, set $n_i := n_i(P)$ and consider $D := |n_rP|$. Then

1. $D$ is a $g^r$ base-point-free on $X$;
2. The $(D, P)$-orders are $n_r - n_i$, $i = 0, \ldots, r$.

In fact, we already noticed that $\text{dim}(D) = r$; $P$ cannot be a base point of $D$ by Lemma 1.19(2)(iv); if $Q \neq P$, then $D := n_rP + \text{div}(1) \in D$ and $v_Q(D) = 0$. This prove (1). To see (2), let $f_i \in F(X)$ such that $\text{div}(f_i) = \text{div}_0(f_i) - n_iP$; cf. Lemma 1.19(2)(iii). Then

$$n_rP + \text{div}(f_i) = (n_r - n_i)P + \text{div}_0(f_i),$$

and the result follows.

Lemma 1.24. Let $f \in F(X)$ such that $\text{div}_\infty(f) = n_1(P)P$. Then $f$ is a separating variable of $F(X)|F$.

Proof. If $F(X)|F(f)$ were not separable, then $f = g^p$, $g \in F(X)$ by [96, Prop. III.9.2]. Then $n_1(P)/p$ would be a non-gap at $P$, a contradiction. □

By definition, a Weierstrass semigroup $H(P)$ belongs to the class of numerical semigroup; i.e., it is a sub-semigroup $H$ of $(N_0, +)$ whose complement in $N_0$, $G(H) := N_0 \setminus H$, is finite. For such a semigroup $H$, $g(H) := \#(N_0 \setminus H)$ is called the genus of $H$. We let $(n_i(H) : i \in N_0)$ (resp. $(\ell_i(H) : i = 1, \ldots, g(H))$) denote the strictly increasing sequence that enumerates $H$ (resp. $G(H)$). Clearly $n_i(H) = g(H) + i$ for $i \geq g(H)$, and $n_i(H) = 2i$ for $i = 1, \ldots, g(H)$ whenever $n_1(H) = 2$. $H$ is called hyperelliptic if $2 \in H$ (note that $2 \in H$ if and only if if $n_1(H) = 2$, whenever $g(H) \geq 1$). This definition is motivated by the so-called hyperelliptic curves, namely those curves admitting a $g^1_2$, or equivalently those admitting rational functions of degree two. Indeed, $X$ is hyperelliptic if and only if there exists $P \in X$ such that $2 \in H(P)$ (see Example 2.28).

Lemma 1.25. (Buchweitz [7, I.3], Oliveira [81, Thm. 1.1]) If $n_1(H) \geq 3$, then $n_i(H) \geq 2i + 1$ for $i = 1, \ldots, g(H) - 2$. In particular, $n_{g-1}(H) \geq 2g(H) - 2$.

The weight of $H$ is $w(H) := \sum_{i=1}^{g(H)} (\ell_i(H) - i)$. It is easy to see that

$$w(H) = (3g(H)^2 + g(H))/2 - \sum_{i=1}^{g(H)} n_i(H),$$

(1.2)
and that \( w(H) = g(H)(g(H) - 1)/2 \) if \( H \) is hyperelliptic. Now Lemma 1.25 and (1.2) imply:

**Corollary 1.26.**

1. \( 0 \leq w(H) \leq g(H)(g(H) - 1)/2 \);
2. \( w(H) = g(H)(g(H) - 1)/2 \) if and only if \( H \) is hyperelliptic;
3. \( w(H) \leq (g(H)^2 - 3g(H) + 4)/2 \) if \( n_1(H) \geq 3 \).

**Remark 1.27.** (Kato [59]) If \( n_1(H) \geq 3 \), we indeed have \( w(H) \leq g(H)(g(H) - 1)/3 \), for \( g(H) = 3, 4, 6, 7, 9, 10 \) and \( w(H) \leq (g(H)^2 - 5g(H) + 10)/2 \), otherwise.

**Definition.** A numerical semigroup \( H \) is called *Weierstrass* if there exist a curve \( X \) and a point \( P \in X \) such that \( H \) equals the Weierstrass semigroup \( H(P) \).

**Remark 1.28.** If \( H \) is Weierstrass, say \( H = H(P) \) on a curve \( X \) of genus \( g = g(H) \), then Lemma 1.25 follows from Castelnuovo’s genus bound (Lemma 1.6): We want to show that

\[
\text{either } g(H) \leq 7, \text{ or } g(H) = 8 \text{ and } 2n_1(H) > \ell_g(H); \text{ see Komeda [63]};
\]

\[
n_1(H) \leq 5; \text{ see Komeda [61], [64], Maclachlan [75, Thm. 4]};
\]

\[
\text{either } w(H) \leq g(H)/2 \text{ or } g(H)/2 < w(H) \leq g(H) - 1 \text{ and } 2n_1(H) > \ell_g(H); \text{ see Eisenbud-Harris [19], Komeda [62]}.
\]

We remark that the underlying curve in these examples is defined over the complex numbers.

In 1893, Hurwitz [57] asked about the characterization of Weierstrass semigroups; see [8, p. 32] and [19, p. 499] for further historical information. Long after that, in 1980 Buchweitz (see Corollary 1.30) showed the existence of a non-Weierstrass semigroup as a consequence of the following.

**Lemma 1.29.** (Buchweitz’s necessary condition, [8, p. 33]) Let \( H \) be a numerical semigroup. For an integer \( n \geq 2 \), let \( nG(H) \) be the set of all sums of \( n \) elements of \( G(H) \). If \( H \) is Weierstrass, then

\[
\#nG(H) \leq (2n - 1)(g(H) - 1).
\]

**Proof.** We have that \( g := g(H) \) is the genus of the underlying curve, say \( X \). For a canonical divisor \( C \) on \( X \), we observe that \( \ell(nC) = (2n - 1)(g - 1) \) by the Riemann-Roch theorem. Let \( \ell := \ell_1 + \ldots + \ell_n \in nG(H) \). From Remark 1.16(iv)(2’), there exists \( f_i \in L(C) \) such that \( v_{\ell_i}(C) + v_{\ell_i}(f_i) = \ell_i - 1 \) for \( i = 1, \ldots, n \). Then \( f_\ell := f_1 \ldots f_n \in L(nC) \) and being the map \( \ell \mapsto f_\ell \) injective, the result follows. \( \square \)
Corollary 1.30. ([8, p. 31]) \{1, \ldots, 12, 19, 21, 24, 25\} is the set of gaps of a numerical semigroup \(H\) of genus 16 which is not Weierstrass.

Proof. We apply the case \(n = 2\) in Lemma 1.29. An easy computations shows that \(2G(H) = [2, 50] \setminus \{39, 41, 47\}\). Then \(#2G(H) = 46 > 3g - 3 = 45\) and so \(H\) cannot be Weierstrass.

In addition, Buchweitz (loc. cit.) showed that for every integer \(n \geq 2\) there exist numerical semigroups which do not satisfy (1.3). Further examples of such semigroups were given in [104, Sect. 4.1] and Komeda [65]. On the other hand, what can we say about semigroups \(H\) that satisfy (1.3) for each \(n \geq 2\)? In fact, there exist at least two classes of such semigroups, namely symmetric semigroups (resp. quasi-symmetric semigroups); i.e., those \(H\) with \(\ell(H) = 2g(H) - 1\) (resp. \(\ell(H) = 2g(H) - 2\)). Indeed, equality in (1.3) for each \(n\) characterize symmetric semigroups (see Oliveira [81, Thm. 1.5]), and Oliveira and Stöhr [82, Thm. 1.1] noticed that \(#nG(H) = (2n - 1)(g - 1) - (n - 2)\) whenever \(H\) is quasi-symmetric. In 1993, Stöhr [103, Scholium 3.5] constructed symmetric semigroups which are not Weierstrass. Indeed, symmetric non-Weierstrass semigroups of any genus larger than 99 can be constructed (loc. cit.) by using the Buchweitz’s semigroup (Corollary 1.30) as a building block. A similar result was obtained for quasi-symmetric semigroups [82, Thm. 5.1] and these examples were generalized in [104, Sect. 4.2]. We stress that any symmetric (resp. quasi-symmetric) semigroup is a Weierstrass semigroup on a Gorenstein (resp. reducible Gorenstein) curve; see [98] (resp. [82]).

Finally, we mention that Hurwitz’s question for numerical semigroups that satisfy (1.3) for each \(n \geq 2\) is currently an open problem.

2. Weierstrass point theory

In this section we study Weierstrass Point Theory of linear series on curves from Stöhr-Voloch’s paper [99, §1]. Other references are Farkas-Kra [22, III.5], Homma [54, Sects. 1,2], Laksoy [71], F.K. Schmidt [88], [89].

Let \(\mathcal{X}\) be a curve over an algebraically closed field \(\mathbf{F}\) of characteristic \(p \geq 0\). Let \(\mathcal{D}\) be a \(g_d^r\) on \(\mathcal{X}\), say \(\mathcal{D} \cong \mathbf{P}(\mathcal{D}') \subseteq |E|\).

In Sect. 1.5, to any point \(P \in \mathcal{X}\) we have assigned a sequence of \((r + 1)\) integers, namely the \((\mathcal{D}, P)\)-orders. Here we study the behaviour of such sequences for general points of \(\mathcal{X}\); i.e, for points in an open Zariski subset of \(\mathcal{X}\). In order to do that we use “wronskians” on \(\mathcal{X}\); i.e., certain functions in \(\mathbf{F}(\mathcal{X})\) defined via derivatives. To avoid restrictions on the characteristic \(p\), we use Hasse derivatives.
2.1. Hasse derivatives. Let \( x \) be a trascendental element over \( F \). For \( i, j \in \mathbb{N}_0 \), set

\[
D^i_x x^j := \binom{j}{i} x^{j-i},
\]

and extend it \( F \)-linearly on \( F[x] \). The \( F \)-linear map \( D^i_x \) is called the \( i \)-th Hasse derivative on \( F[x] \). \( i! \) \( D^i_x x^j \) is the usual \( i \)-th derivative \( \frac{d^i}{dx^i} \), and \( D^i_x x^i \neq 0 \), as \( D^i_x x^i = 1 \), but \( \frac{d^i}{dx^i} = 0 \) for \( i > 0 \).

**Remark 2.1.** For \( f(x) \in F[x] \), \( D^i_x f(x) \) is the coefficient of \( u^i \) in the expansion of \( f(x+u) \) as a polynomial in \( u \).

The \( F \)-linear maps \( D^i_x \), \( i \in \mathbb{N}_0 \), satisfy the following four properties:

- **(H1)** \( D^0_x = \text{id} \);
- **(H2)** \( D^i_x|_F = 0 \) for \( i \geq 1 \);
- **(H3)** \( D^i_x(fg) = \sum_{j=0}^i D^j_x f D^{i-j}_x g \) (Product Rule);
- **(H4)** \( D^i_x \circ D^j_x = \binom{i+j}{i} D^{i+j}_x \).

Properties (H1), (H2) and (H4) easily follow from the definition of \( D^i_x \), while (H3) follows by comparing the coefficients of \( (fg)(x+u) \) and \( f(x+u)g(x+u) \).

Next one extends \( D^i_x \) to \( F(x) \) and then to each finite separable extension of \( F(x) \). This is done in just one way; moreover, the extended map remains \( F \)-linear and still satisfies the four aforementioned properties. The extension on \( F(x) \) is constructed as follows. By (H1) and (H3) it is enough to define \( D^i_x(1/f) \) for \( i \geq 1 \) and \( f \neq 0 \). From \( f(1/f) = 1 \), (H2) and (H3) one finds the following recursive formula:

\[
\sum_{j=0}^i D^j_x(1/f) D^{i-j}_x f = 0.
\]

For \( i = 1 \) one obtains the expected relation \( D^1_x(1/f) = -D^1_x f/f^2 \), and in general [38, p. 119]

\[
D^i_x(1/f) = \sum_{j=1}^i \frac{(-1)^j}{f^{j+1}} \sum_{i_1, \ldots, i_j \geq 1; \ i_1 + \ldots + i_j = i} D^{i_1}_x f \ldots D^{i_j}_x f.
\]

**Remark 2.2.** The maps \( D^i_x \) on \( F(x) \), \( i \in \mathbb{N}_0 \), are characterized by the following four properties:

(i) they are \( F \)-linear;
(ii) they satisfy (H1) and (H3) above;
(iii) \( D^1_x x = 1 \);
(iv) \( D^i_x x = 0 \) for \( i \geq 2 \).
To see this, let $\eta_i, i \in \mathbb{N}_0$, be maps on $F(x)$ satisfying (i), (ii), (iii) and (iv). From the formula for $D_x^i(1/f)$ above, is enough to show that $\eta_i(x^j) = D_x^i x^j$ (*). Now, since the $\eta_i$’s satisfy (H3), it follows [47, Lemma 3.11]

\begin{equation}
\eta_i(x^j) = j x^j - 1 \eta_i(x) + \sum_{\ell=2}^{j} \sum_{m=1}^{i-1} x^{j-\ell} (\eta_i(x)) (\eta_i(x^{\ell-1})),
\end{equation}

and we obtain (*) by induction on $i$ and $j$.

**Remark 2.3.** The maps $D_x^i, i \in \mathbb{N}_0$, on $F(x)$ have also a unique extension to the Laurent series $F((x))$ which satisfy (H1), (H2), (H3), and (H4) above. One sets $D_x^i(\sum_j a_j x^j) := \sum_j \binom{j}{i} a_j x^{j-i}$, see [47, p. 12].

Next we extend $D_x^i$ to a finite separable extension $K|F(x)$. Let $y \in K$ be such that $K = F(x, y)$, and $F(x)(Y)$ the minimal polynomial of $y$ over $F(x)$. Then we define $D_x^i y^m$ by using $F(x, y) = 0$ and (2.1). For example, for $i = 1$ we obtain

\begin{equation}
F_Y(x, y) D_x^1 y + \sum_j (D_x^1 a_j(x)) y^j = 0,
\end{equation}

so that $D_x^1 y$ is well defined as $F_Y(x, y) \neq 0$. Notice that these extensions satisfy (H1), (H2), (H3) and (H4) above and depend on the element $y$. However, it is a matter of fact that the $F$-linear maps $D_x^i$ on $F(x)$ admit a unique extension to $F$-linear maps on $K$ satisfying the aforementioned (H1), (H2), (H3), and (H4); see [46].

Therefore, $F(\mathcal{X})$ is equipped with $F$-linear maps $D_x^i$ such that (H1), (H2), (H3) and (H4) above hold true, with $x$ being a separating variable of $F(\mathcal{X})|F$. If $y$ is another separating variable of $F(\mathcal{X})|F$, relations among the $D_x^i$’s and the $D_y^j$’s are given by the so called chain rule; see (2.3) and (2.4).

**Remark 2.4.** For $i \in \mathbb{N}_0$, let $D^i$ be $F$-linear maps on a $F$-algebra $K$ satisfying (H1), (H2), (H3) and (H4) above. From (H4),

$$i! D^i = (D^1)^i := D^1 \circ \ldots \circ D^1 \ i \ \text{times},$$

so that each $D^i$ is determined by $D^1$ provided that $p = 0$. Suppose now $p > 0$.

**Claim.** Let $0 \leq a, b < p, \alpha, \beta \in \mathbb{N}$. Then

1. $D^{ap^\alpha + bp^\beta} = D^{ap^\alpha} \circ D^{bp^\beta}$.
2. $D^{ap^\alpha} = (D^{p^\alpha})^a / a!$.

**Proof.** The statements are consequence of (H4) and the following property of binomial numbers: if $i = \sum_\alpha a^\alpha p^\alpha, j = \sum_\alpha b^\alpha p^\alpha$ are the $p$-adic expansion of $i, j \in \mathbb{N}$, then $\binom{i}{j} = \prod_\alpha \binom{a^\alpha}{b^\alpha}$.

Therefore in positive characteristic the $D^i$’s are determined by $D^1, D^p, D^{p^2}, \ldots$. 

A $\mathbb{F}$-linear map $D$ on $\mathbb{F}(\mathcal{X})$ satisfying $D(fg) = fD(g) + gD(f)$, is called a $\mathbb{F}$-derivation on $\mathbb{F}(\mathcal{X})$. For example, $D_x^1$ is a derivation on $\mathbb{F}(\mathcal{X})$, where $x$ is a separating variable of $\mathbb{F}(\mathcal{X})|\mathbb{F}$. From (2.1) follows that two $\mathbb{F}$-derivations $\delta_1$ and $\delta_2$ on $\mathbb{F}(\mathcal{X})$ are equal if $\delta_1(x) = \delta_2(x)$.

Now let $y$ be another separating variable of $\mathbb{F}(\mathcal{X})|\mathbb{F}$. Since the $\mathbb{F}$-derivations $\delta_1 := D_y^1$ and $\delta_2 := D_y^1(x)D_x^1$ satisfy $\delta_1(x) = \delta_2(x)$, we obtain the usual chain rule, namely

\[ \tag{2.3} D_y^1 = D_y^1(x)D_x^1. \]

To generalize this relation to higher derivatives, let $T$ be a trascendental element over $\mathbb{F}(\mathcal{X})$. The maps $D_x^i$ and $D_y^i$ can be read off from the homomorphisms of $\mathbb{F}$-algebras $\eta_x, \eta_y$: $\mathbb{F}(\mathcal{X}) \to \mathbb{F}(\mathcal{X})[[T]]$ defined respectively by

\[ \eta_x(f) := \sum_{i \geq 0} D_x^i(f)T^i, \quad \text{and} \quad \eta_y(f) := \sum_{i \geq 0} D_y^i(f)T^i. \]

Let $h: \mathbb{F}(\mathcal{X})[[T]] \to \mathbb{F}(\mathcal{X})[[T]]$ be the $\mathbb{F}$-homomorphism defined by $h|_{\mathbb{F}(\mathcal{X})} = \text{id}_{\mathbb{F}(\mathcal{X})}$ and $h(T) := \sum_{i \geq 1} D_y^i(x)T^i$. Since $D_y^1(x) \neq 0$ by (2.3), $h$ is an automorphism of $\mathbb{F}(\mathcal{X})[[T]]$. Consider the $\mathbb{F}$-homomorphism $\eta: \mathbb{F}(\mathcal{X}) \to \mathbb{F}(\mathcal{X})[[T]]$ given by $\eta := h^{-1} \circ \eta_y$. For $f \in \mathbb{F}(\mathcal{X})$, set $\eta(f) := \sum_{i \geq 0} \eta_i(f)T^i$. Then the maps $\eta_i$ are $\mathbb{F}$-linear on $\mathbb{F}(\mathcal{X})$ and satisfy properties (H1) and (H3) above. Write $h(T) = TU$, $U = D_y^1(x) + D_y^2(x)T + \ldots$.

Claim. Let $i \in \mathbb{N}_0$ and $f \in \mathbb{F}(\mathcal{X})$. Then $\eta_0(f) = D_y^0(f)$ and for $i \geq 1$ the following holds

\[ D_y^i(f) = \sum_{j=1}^{i} a_j \eta_j(f), \]

where $a_j$ is the coefficient of $T^{i-j}$ in $U^j$. In particular, $a_1 = D_y^1(x)$, $a_i = (D_y^1)x^i$.

Proof. Write $\eta_y = h \circ \eta$. The coefficient of $T^i$ in $(h \circ \eta)(f)$ can be read off from $\sum_{j=0}^{i} a_j(f)(TU)^j$, and the claim follows.

Then we have $\eta_1(x) = 1$ and $\eta_i(x) = 0$ for $i \geq 2$. Therefore from Remark 2.2, $\eta_i = D_x^i$ on $\mathbb{F}(x)$ and hence also on $\mathbb{F}(\mathcal{X})$. This implies the generalized chain rule:

\[ \eta_y = h \circ \eta_x, \]

or equivalently

\[ \tag{2.4} D_y^i = \sum_{j=1}^{i} f_j D_x^j, \quad i = 1, 2, \ldots, \]

where $f_j \in \mathbb{F}(|D_y^m(x): m = 1, 2, \ldots|)$. Observe that $f_1 = D_y^1(x)$ and $f_i = (D_y^1x)^i$.

Remark 2.5. We mention two further properties of Hasse derivatives regarding prime powers of rational functions. Let $f \in \mathbb{F}(\mathcal{X})$, $x$ a separating variable of $\mathbb{F}(\mathcal{X})|\mathbb{F}$, and $q$ a power of $p = \text{char}(\mathbb{F}) > 0$. We have
(i) $D_x^i f^q = (D_x^{i/q})^q f^q$ if $q$ divides $i$, and $D_x^i f^q = 0$ otherwise;
(ii) \([46, \text{ Satz 10}]\) \( \exists g \in F(\mathcal{X}) \) such that \( f = g^q \) if and only if $D_x^i(f) = 0$ for $i = 1, \ldots, q - 1$.

**Definition.** A *wronskian* on $\mathcal{X}$ is a rational function of type

\[
W_{f_0, \ldots, f_r; x} := \det((D_x^\ell f_j)),
\]

where \( \ell_0 < \ldots < \ell_r \) is a sequence of non-negative integers, $x$ is a separating variable of $F(\mathcal{X})|F$, and $f_0, \ldots, f_r \in F(\mathcal{X})$. We set

\[
\mathcal{A}(f_0, \ldots, f_r; x) := \{(m_0, \ldots, m_r) \in \mathbb{N}_0^{r+1} : m_0 < \ldots < m_r; W_{f_0, \ldots, f_r; x}^{m_0, \ldots, m_r} \neq 0\}.
\]

### 2.2. Order sequence; Ramification divisor

Let \( P \in \mathcal{X} \) and $t$ be a local parameter at $P$. Let

\[
j_0 = j_0(P) < \ldots < j_r = j_r(P)
\]
denote the \((\mathcal{D}, P)\)-orders. From Remark 1.16(iii)(3) there exists $f_\ell \in F(\mathcal{X})$ such that

\[
v_p(t^{v_p(E)} f_\ell) = j_\ell, \quad \ell = 0, \ldots, r.
\]

**Claim.** \( \{f_0, \ldots, f_r\} \) is a $F$-base of $\mathcal{D}'$.

**Proof.** If there exists a non-trivial relation \( \sum_i a_i f_i = 0 \) with \( a_i \in F \), then we would have \( v_p(f_i) = v_p(f_i) \) for \( i \neq \ell \) and so \( j_i = j_\ell \), a contradiction. \qed

**Definition.** The aforementioned $F$-base \( \{f_0, \ldots, f_r\} \) is called a \((\mathcal{D}, P)\)-base (or \((\mathcal{D}, P)\)-Hermitian base).

**Remark 2.6.** Let \( \{f_0, \ldots, f_r\} \) be a \((\mathcal{D}, P)\)-base. For \( i = 0, \ldots, r \), \( \mathcal{D}'_{j_i}(P) = \mathcal{D}' \cap L(E - j_i P) \) so that

\[
\mathcal{D}'_{j_i}(P) = \langle f_i, \ldots, f_r \rangle,
\]

or equivalently

\[
\mathcal{D}_{j_i}(P) = \{E + \text{div}\left(\sum_{\ell=i}^{r} a_\ell f_\ell\right) : (a_i : \ldots : a_r) \in \mathbb{P}^{r-i}(F)\}.
\]

Thus

\[
j_i(P) = \min\left\{v_p\left(\sum_{\ell=i}^{r} a_\ell t^{v_p(E)} f_\ell\right) : (a_i : \ldots : a_r) \in \mathbb{P}^{r-i}(F)\right\}.
\]

Let \( \{f_0, \ldots, f_r\} \) be a \((\mathcal{D}, P)\)-base. Set \( g_\ell := t^{v_p(E)} f_\ell \).

**Lemma 2.7.** If \( m_0 < \ldots < m_r \) is a sequence of non-negative integers such that \( \det((j_i^{m_i})_{m_i}) \neq 0 \mod p \), then \( (m_0, \ldots, m_r) \in \mathcal{A}(g_0, \ldots, g_r; t) \). In particular, \( (j_0, \ldots, j_r) \in \mathcal{A}(g_0, \ldots, g_r; t) \).
Proof. Let \( g_\ell = \sum_{s=j_\ell}^{\infty} c_{j_\ell}^{s} t^s \), \( c_{j_\ell}^{s} \neq 0 \), be the local expansion of \( g_\ell \) at \( P \). Set \( C := \prod_{\ell=0}^{r} c_{j_\ell}^{s} \). Then

\[
W_{g_0, \ldots, g_r, t}^{m_0, \ldots, m_r} = \det \left( \sum_{s=j_\ell}^{\infty} \left( \frac{s}{m_i} \right) c_{j_\ell}^{s} t^{s-m_i} \right)
\]

\[
= C t^{-\sum_i m_i} \det \left( \sum_{s=j_\ell}^{\infty} \left( \frac{s}{m_i} \right) c_{j_\ell}^{s} t^{s} \right)
\]

\[
= C \det \left( \left( \frac{j_\ell}{m_i} \right) t^{\sum_i (j_i-m_i) + \ldots} \right) \neq 0,
\]

and the result follows. \( \square \)

For \( \ell \in \mathbb{N}_0 \), set \( D^\ell \phi := (D^\ell g_0, \ldots, D^\ell g_r) \). Since each coordinate of this vector is regular at \( P \), we also set \( (D^\ell g_0)(P), \ldots, (D^\ell g_r)(P) \).

Then, for \( 0 \leq m_0 < \ldots < m_r \), \((m_0, \ldots, m_r) \in \mathcal{A}(g_0, \ldots, g_r; t)\) if and only if \( D^{m_0}_t \phi, \ldots, D^{m_r}_t \phi \) are \( \mathbf{F}(\mathcal{A}) \)-linearly independent.

**Scholium 2.8.**

1. Set \( j_{-1} := 0 \). For \( i = 0, \ldots, r \),

\[
j_i = j^{D}_i(P) = \min \{ s > j_{i-1} : (D^s_i \phi)(P), \ldots, (D^{j_i-1}_i \phi)(P), (D^{j_i}_i \phi)(P) \} \text{ are } \mathbf{F} \text{-l.i.} \};
\]

2. Let \( m_0 < \ldots < m_r \) be non-negative integers, with \( r' \leq r \), such that the vectors \((D^{m_0}_t \phi)(P), \ldots, (D^{m_{r'}}_t \phi)(P)\) are \( \mathbf{F} \)-linearly independent. Then \( j_i \leq m_i \) for \( i = 0, \ldots, r' \).

**Proof.** (1) From Lemma 2.7 and its proof, the vectors \((D^0_i \phi)(P), \ldots, (D^{j_i}_i \phi)(P)\) are \( \mathbf{F} \)-linearly independent and

\[
D^{j_i}_i g_\ell(P) = \begin{cases} 
0 & \text{if } \ell > i, \\
c_{j_i}^{\ell} & \text{if } \ell = i, \\
c_{j_i}^{\ell} & \text{if } \ell < i.
\end{cases}
\]

Let \( j_{i-1} < s < j_i \). For \( \ell = 0, \ldots, i-1 \), we have vectors of type

\[
(D^s_i \phi)(P) = (\ast, \ldots, \ast, c_{j_i}^{\ell}, 0, \ldots, 0),
\]

with \((r-\ell)\) zeros and where \( \ast \) denotes an element of \( \mathbf{F} \). Since the last \((r-i+1)\) entries of the vector \((D^s_i \phi)(P)\) are zeroes, (1) follows.

(2) From (1), \( \dim_{\mathbf{F}} \{ (D^s \phi)(P) : s = 0, \ldots, j_i - 1 \} = i \) so that \( j_i - 1 < m_i \). \( \square \)

In \( \mathbb{Z}^{r+1} \) we have a partial order given by the so-called lexicographic order \( < \). For \( \alpha, \beta \in \mathbb{Z}^{r+1} \), \( \alpha < \beta \) if in the vector \( \beta - \alpha \) the left most non-zero entry is positive. This order is a well-ordering on \( \mathbb{N}^{r+1} \), see e.g. [16, p. 55]. Let

\[
\mathcal{E} := (\epsilon_0, \ldots, \epsilon_r)
\]

be the minimum (in the lexicographic order) of \( \mathcal{A}(g_0, \ldots, g_r; t) \).
Proposition 2.11.  

(1) \( \epsilon_0 = 0; \)

(2) \( \epsilon_1 = 1 \) whenever \( p \) does not divide \( \deg(D) - \deg(B^D); \)

(3) For \( i = 1, \ldots, r, \)

\[
\epsilon_i = \min \{ s > \epsilon_i-1 : D_t^{i-1} \phi, \ldots, D_t^0 \phi, D_t^0 \phi \text{ are } F(\mathcal{X})\text{-l.i.} \}.
\]

Proof. (1) Suppose that \( \epsilon_0 > 0. \) Then \( D_t^0 \phi = \sum_{j=1}^r h_j D_t^j \phi \) with some \( h_{j_0} \in F(\mathcal{X})^*, \) because \( (0, \epsilon_1, \ldots, \epsilon_r) < \mathcal{E}. \) Then we replace the row \( D_t^{j_0} \phi \) by \( D_t^0 \phi \) in \( W_{\epsilon_0, \ldots, \epsilon_r}^r; \) so that \( (0, \epsilon_0, \ldots, \epsilon_{j_0-1}, \epsilon_{j_0+1}, \ldots, \epsilon_r) \in \mathcal{A}(g_0, \ldots, g_r; t), \) a contradiction to the minimality of \( \mathcal{E}. \)

(2) As in part (1) we have that \( \epsilon_1 = 0 \) if and only if \( D_t^1 g_\ell = 0 \) (or equivalently \( D_t^i g_\ell = 0 \) for \( 1 \leq i < p \)) for any \( \ell = 0, \ldots, r. \) Then each \( g_\ell \) is a \( p \)-power by Remark 2.5(ii), and so \( p \) divides \( v_p(E) - b(P) \) by Lemma 1.4; i.e., \( p \) divides \( \deg(D) - \deg(B^D). \)

(3) Clearly \( D_t^0 \phi, \ldots, D_t^{r} \phi \) are \( F(\mathcal{X})\)-linearly independent. Let \( \epsilon_{i-1} < s < \epsilon_i. \) Since \( (\epsilon_0, \ldots, \epsilon_{i-1}, s, \epsilon_{i+1}, \ldots, \epsilon_r) < \mathcal{E}, \) there exists a relation of type

\[
D_t^s \phi = \sum_{j=0}^{i-1} h_j D_t^j \phi + \sum_{j=i+1}^r h_j D_t^j \phi,
\]

with \( h_j \in F(\mathcal{X}). \) We claim that \( h_j = 0 \) for \( j \geq i + 1. \) Indeed, suppose that \( h_{j_0} \neq 0 \) for some \( j_0 \geq i + 1. \) Then by replacing \( D_t^{j_0} \phi \) by \( D_t^0 \phi \) in \( W_{\epsilon_0, \ldots, \epsilon_r}^r; \) we would have that \( (\epsilon_0, \ldots, \epsilon_{i-1}, s, \epsilon_{i+1}, \ldots, \epsilon_{j_0-1}, \epsilon_{j_0+1}, \ldots, \epsilon_r) \in \mathcal{A}(g_0, \ldots, g_r; t), \) a contradiction to the minimality of \( \mathcal{E}. \) This finish the proof. \( \square \)

Corollary 2.10.  

(1) Let \( (m_0, \ldots, m_r) \in \mathcal{A}(g_0, \ldots, g_r; t). \) Then for each \( i, \) \( \epsilon_i \leq m_i. \)

In particular, \( \epsilon_i \leq j_i = j_i(P); \)

(2) If \( 0 \leq m_0 < \ldots < m_r \) are integers such that \( \det((\epsilon_i/j_i)) \neq 0 \text{ (mod p), then } \epsilon_i \leq m_i \) for each \( i. \)

Proof. From Lemma 2.9,

\[
\{D_t^i \phi : \ell = 0, \ldots, \epsilon_i - 1\} = \langle \{D_t^i \phi : j = 0, \ldots, i - 1\}\rangle.
\]

If \( \epsilon_i > m_i, \) we would have

\[
\dim_{F(\mathcal{X})}(\{D_t^i \phi : \ell = 0, \ldots, \epsilon_i - 1\}) \geq \dim_{F(\mathcal{X})}(\{D_t^{m_i} \phi : \ell = 0, \ldots, i\}) \geq i + 1,
\]

a contradiction. This proves (1). Now (2) follows from Lemma 2.7 and (1). \( \square \)

Proposition 2.11.  

(1) If \( h_i = \sum a_{ij} g_j \) with \( (a_{ij}) \in M_{r+1}(F), \) then

\[
W_{\epsilon_0, \ldots, \epsilon_r}^{h_0, \ldots, h_r; t} = \det((a_{ij}))W_{\epsilon_0, \ldots, \epsilon_r}^{g_0, \ldots, g_r; t};
\]

(2) If \( f \in F(\mathcal{X}), \) then

\[
W_{f, \epsilon_0, \ldots, \epsilon_r}^{g_0, \ldots, g_r; t} = f^{r+1} W_{\epsilon_0, \ldots, \epsilon_r}^{g_0, \ldots, g_r; t};
\]

(3) Let \( x \) be any separating variable of \( F(\mathcal{X})|F. \) Then

\[
W_{\epsilon_0, \ldots, \epsilon_r}^{g_0, \ldots, g_r; x} = (D_x t) \sum_{i} \epsilon_i W_{\epsilon_0, \ldots, \epsilon_r}^{g_0, \ldots, g_r; t}.
\]
Proof. (1) It follows from $D_t^\epsilon h_i = \sum a_{ij} D_t^{\epsilon_j} g_j$. Note that this result does not depend on the minimality of $E$.

(2) By the product rule (cf. Sect. 2.1), we have

$$D_t^{\epsilon_i} (fg) = \sum_{\ell=0}^{\epsilon_i} D_t^{\ell} f D_t^{\epsilon_i-\ell} g_j .$$

Then

$$(D_t^{\epsilon_i} fg_0, \ldots, D_t^{\epsilon_i} fg_r) = f D_t^{\epsilon_i} \phi + \sum_{\ell=1}^{\epsilon_i} D_t^{\ell} f D_t^{\epsilon_i-\ell} \phi .$$

By (2.5) we can factor out $f$ in each row of $W_{fg_0, \ldots, fgr}^{\epsilon_0, \ldots, \epsilon_r}$, and (2) follows.

(3) The proof is similar to (2) but here we use the chain rule (2.4) instead of the product rule. We have

$$D_x^{\epsilon_i} g_j = \sum_{\ell=1}^{\epsilon_i} f_{\ell} D_t^{\ell} g_j ,$$

where $f_{\ell} \in F(\mathcal{X})$ and $f_{\epsilon_i} = (D_t^{1} t)^{\epsilon_i}$. Hence

$$D_x^{\epsilon_i} \phi = (D_x^{1} t)^{\epsilon_i} D_t^{\epsilon_i} \phi + \sum_{\ell=1}^{\epsilon_i-1} f_{\ell} D_t^{\ell} \phi ,$$

and again by (2.5) we can factor out $(D_x^{1} t)^{\epsilon_i}$ in each row of $W_{fg_0, \ldots, fgr}^{\epsilon_0, \ldots, \epsilon_r}$. \qed

Now we see that $E$ depends only on $\mathcal{D}$: Let $f_0', \ldots, f_r'$ be any $F$-base of $\mathcal{D}'$ and $x$ any separating variable of $F(\mathcal{X}) | F$; since $g_{\ell} = t^{\epsilon_{\ell}(E)} f_{\ell}$, from Proposition 2.11(1)(2) $E$ is the minimum for $\mathcal{A}(f_0', \ldots, f_r'; t)$. Moreover by part (3) of that proposition, $E$ is also the minimum for $\mathcal{A}(g_0, \ldots, g_r; x)$. Finally, from part (2), $E$ is also the minimum for $\mathcal{A}(f_0', \ldots, f_r'; x)$.

**Definition.** $E = E_{\mathcal{D}}$ is called the *order sequence* of $\mathcal{D}$. The *order sequence* of a morphism $\phi$ is the order sequence of $\mathcal{D}_\phi$.

**Remark 2.12.** Let $m_0 < \ldots < m_r$ be a sequence of non-negative integers such that $\det \binom{j_i}{m_i} \neq 0 \pmod{p}$. Then $\epsilon_i \leq m_i$ for each $i$ by Corollary 2.10(2). We shall discuss the best election of the $m_i$’s. In Example 1.18 we have seen that the $(\mathcal{D}, P)$-orders $j_0 < \ldots < j_r$ are the $(\mathcal{D}_\phi, P_0)$-orders for $\phi = (x^{j_0} : \ldots : x^{j_r}) : \mathbf{P}^1(F) \to \mathbf{P}^r$ and $P_0 = (1 : 0)$. Observe that

$$W_{x^{j_0}, \ldots, x^{j_r}; x}^{m_0 \ldots \ldots m_r} = \det \binom{j_\ell}{m_i} x^{\sum \epsilon_i (j_i - m_i)} .$$

Let $\eta_0, \ldots, \eta_r$ be the $\mathcal{D}_\phi$-orders. Then

1. $\det \binom{j_i}{n_i} \neq 0 \pmod{p}$ by (2.6) with $n_i = \eta_i$, and the definition of $\mathcal{D}_\phi$-orders;
2. $\eta_\ell \leq m_\ell$ for each $\ell$ by (2.6) with $n_i = m_i$, and Scholium 2.8(2).

This shows that the best way to upper bound the $\epsilon_i$’s is by means of the sequence $\eta_0, \ldots, \eta_r$.

In addition, from (2.6) and Lemma 2.9 applied to $\mathcal{D}_\phi$, we obtain the following.
Corollary 2.13. Let \( i \in \{0, \ldots, r\} \) and let \( m_0 < \ldots < m_i \) be non-negative integers, such that the vectors \( \left( \binom{j_0}{m_i}, \ldots, \binom{j_r}{m_i} \right) \), \( \ell = 0, \ldots, i \) are \( \mathbb{F}_p \)-linearly independent. Then \( \epsilon_\ell \leq m_\ell \) for \( \ell = 0, \ldots, i \).

Corollary 2.14. (Esteves, [20])

\[
\epsilon_i + J_\ell(P) \leq J_{i+\ell}(P), \quad i + \ell \leq r.
\]

Proof. (Following Homma [56]) By means of suitable central projections [20, Lemma 2] one can assume that \( i + \ell = r \). Let \( D_\phi \) be the linear series on \( \mathbb{P}^1(\mathbb{F}) \) in Remark 2.12, and \( \eta_0, \ldots, \eta_r \) the \( D_\phi \)-orders. By Example 1.18, \( j_r - j_r - j_r - \ldots, j_r - j_0 \) are the \((D_\phi, (0:1))\)-orders. Then, for each \( i, j_r - j_{r-i} \geq \eta_i \geq \epsilon_i \) by Corollary 2.10(1) and Remark 2.12, and the result follows.

Remark 2.15. Corollary 2.14 was first noticed by Homma [55] for \( D \)-orders; see also [28] and [56].

Now we define the so-called ramification divisor of \( D \). Let \( f'_0, \ldots, f'_r \) be any base of \( D' \) and \( x \) any separating variable of \( F(X)/F \). As before let \( P \in X \), \( t \) a local parameter at \( P \), \( \{f_0, \ldots, f_r\} \) a \((D, P)\)-base; set \( g_\ell = t^{\nu_\ell(E)}f_\ell \). We have a matrix \( (a_{ij}) \in GL(r+1, \mathbb{F}) \) such that \( f'_i = \sum_j a_{ij}f_j \) for each \( i \). Proposition 2.11 implies

\[
W_{f'_0, \ldots, f'_r}^{\epsilon_0, \ldots, \epsilon_r} = \det(a_{ij})W_{f_0, \ldots, f_r}^{\epsilon_0, \ldots, \epsilon_r} = \det(a_{ij})t^{-(r+1)\nu_\ell(E)}W_{g_0, \ldots, g_r}^{\epsilon_0, \ldots, \epsilon_r}
\]

i.e.,

\[
(2.7) \quad W_{f'_0, \ldots, f'_r}^{\epsilon_0, \ldots, \epsilon_r}(D^1tX)\sum_i \epsilon_i t^{(r+1)\nu_\ell(E)} = \det(a_{ij})W_{g_0, \ldots, g_r}^{\epsilon_0, \ldots, \epsilon_r}.
\]

Thus the divisor

\[
R = R^D := \text{div}(W_{f'_0, \ldots, f'_r}^{\epsilon_0, \ldots, \epsilon_r}) + \sum_{i=0}^r \epsilon_i \text{div}(dx) + (r+1)E,
\]

just depends on \( D \) and locally is given by (2.7).

Definition. \( R \) is called the ramification divisor of \( D \). The ramification divisor of a morphism \( \phi \) is the ramification divisor of \( D_\phi \).

Example 2.16. Let \( x \) be a separating variable of \( F(X)/F \) and consider the morphism \( \phi = (1: x): X \to \mathbb{P}^1(\mathbb{F}) \). Then \( E_\phi = \text{div}_\infty(x) \); moreover, as \( \#x^{-1}(x(P)) = \deg(\text{div}_\infty(x)) \) for infinitely many \( P \in X \), the \( D_\phi \)-orders are 0,1. Then

\[
R^{D_\phi} = \text{div}(dx) + 2\text{div}_\infty(x);
\]

i.e., it coincides with the ramification divisor \( R_x \) of \( x \), see Example 1.1.
Lemma 2.17. (Garcia-Voloch [33, Thm. 1]) Let $\phi = (f_0 : \ldots : f_r)$ be a morphism associated to $D$, and $q'$ a power of $\text{char}(F) > 0$. Then $\epsilon_r \geq q'$ if and only if there exist $z_0, \ldots, z_r \in F(X)$, not all zero, such that

$$z_0^{q'}f_0 + \ldots + z_r^{q'}f_r = 0.$$ 

Corollary 2.18. Let $P \in X$. Under the hypothesis of the previous lemma, there exist $i, \ell \in \{0, \ldots, r\}, i \neq \ell$, such that $j_i(P) \equiv j_{\ell}(P) \pmod{q'}$.

Proof. We can assume that $f_0, \ldots, f_r$ is a $(D, P)$-base. Now there exist $0 \leq i < \ell \leq r$ such that $v_P(z_i^{q'}f_i) = v_P(z_{\ell}^{q'}f_{\ell})$ and the result follows.

2.3. $D$-Weierstrass points. Let us keep the notation of the previous subsection. Now we study $R$ locally at $P$ via (2.7); i.e., we study

$$v_P(R) = v_P(W_{g_0, \ldots, g_r}).$$

We observe that $v_P(R) \geq 0$ since $g_\ell$ is regular at $P$ for each $\ell$.

Theorem 2.19. (1) $v_P(R) \geq \sum_{i=0}^{r} (j_i(P) - \epsilon_i)$;

(2) $v_P(R) = \sum_{i=0}^{r} (j_i(P) - \epsilon_i) \Leftrightarrow \det((j_i(P))) \not\equiv 0 \pmod{p}$.

Proof. Set $j_i := j_i(P)$. From the proof of Lemma 2.7 with $m_i = \epsilon_i$ we have a local expansion of type

$$W_{g_0, \ldots, g_r} = C\det\left(\begin{array}{c} j_i \\ \epsilon_i \end{array}\right)t^{\sum (j_i - \epsilon_i)} + \ldots,$$

with $C \in F^*$ and the result follows.

We have already observed that $R$ is an effective divisor which also follows from $j_i(P) \geq \epsilon_i$ (cf. Corollary 2.10(1)). Moreover, the following is clear from the theorem.

Corollary 2.20. $v_P(R) = 0$ if and only if $j_i(P) = \epsilon_i$ for each $i$. In particular, for all but finitely many $P \in X$, the $(D, P)$-orders equal $\epsilon_0, \ldots, \epsilon_r$.

Definition. The $D$-Weierstrass points of $X$ are those of $\text{Supp}(R)$. The $D$-weight of $P$ is $v_P(R)$.

Thus the number of $D$-Weierstrass points of $X$, counted with their weights, equals

$$\text{deg}(R) = (\sum_{i=0}^{r} \epsilon_i)(2g - 2) + (r + 1)d.$$ 

Lemma 2.21. ($p$-adic criterion) Let $\epsilon$ be a $D$-order and let $\mu$ be an integer such that $\binom{\mu}{\epsilon} \not\equiv 0 \pmod{p}$. Then $\mu$ is also a $D$-order. In particular, $0, 1, \ldots, \epsilon - 1$ are $D$-orders provided that $p > \epsilon$. 

Proof. Let \( \ell \in \{0, \ldots, r-1\} \) be such that \( \epsilon_\ell < \mu \leq \epsilon_{\ell+1} \leq \epsilon \). We apply Corollary 2.13 to a point \( P \notin \text{Supp}(R) \); i.e., such that \( j_i(P) = \epsilon_i \) for each \( i \). Let \( m_0 = \epsilon_0, \ldots, m_\ell = \epsilon_\ell, m_{\ell+1} := \mu \). Then the vectors \( \left( \begin{pmatrix} \epsilon_0 \\ m_0 \end{pmatrix}, \ldots, \begin{pmatrix} \epsilon_\ell \\ m_\ell \end{pmatrix} \right), s = 0, \ldots, \ell+1 \), are \( \mathbb{F}_p \)-linearly independent and the result follows.

Definition. The curve \( \mathcal{X} \) is called classical with respect to \( \mathcal{D} \), or the linear series \( \mathcal{D} \) is called classical, if the \( \mathcal{D} \)-orders are \( 0, \ldots, r \). A morphism \( \phi \) is called classical if \( \mathcal{D}_\phi \) is classical.

Lemma 2.22. Suppose that \( \prod_{i=\ell}^{r} \frac{j_i(P) - j_i(P)}{i-\ell} \neq 0 \pmod{p} \). Then

1. \( \mathcal{D} \) is classical;
2. \( v_P(R) = \sum_{i=0}^{r}(j_i(P) - i) \).

Proof. (1) Set \( j_i = j_i(P) \). We have
\[
\det\left( \begin{pmatrix} j_i \\ \ell \end{pmatrix} \right) = \prod_{i > \ell} \frac{j_i - j_\ell}{i - \ell} \not\equiv 0 \pmod{p},
\]
by hypothesis. Then \( \epsilon_i \leq i \) by Corollary 2.10(2); i.e., \( \epsilon_i = i \) for each \( i \).

(2) Follows from Theorem 2.19(2).

In particular, as \( j_r(P) \leq d = \deg(\mathcal{D}) \), we obtain:

Corollary 2.23. If \( p = 0 \) or \( p > d = \deg(\mathcal{D}) \), then

1. \( \mathcal{D} \) is classical;
2. For each \( P \in \mathcal{X} \), \( v_P(R) = \sum_{i}(j_i(P) - i) \).

2.4. \( \mathcal{D} \)-osculating spaces. Assume that \( \mathcal{D} \) is base-point-free, \( \mathcal{D} = g_\phi^* \cong \mathbb{P}^r(\mathcal{D}') \subseteq |E| \). From Remark 1.14,

\( \mathcal{D} = \{ \phi^*(H) : H \text{ hyperplane in } \mathbb{P}^r \} \),

where \( \phi = (f_0 : \cdots : f_r) \), and where \( \{f_0, \ldots, f_r\} \) is a \( \mathbb{F} \)-base of \( \mathcal{D}' \). Let \( P \in \mathcal{X} \) with \((\mathcal{D}, P)\)-orders \( j_0 < \cdots < j_r \). From Lemma 1.4,

\( v_P(E) = -\min\{v_P(f_0), \ldots, v_P(f_r)\} \).

For \( i = 0, \ldots, r-1 \), let \( L_i^{f_0, \cdots, f_r}(P) \) be the intersection of the hyperplanes \( H \) in \( \mathbb{P}^r \) such that \( v_P(\phi^*(H)) \geq j_{i+1} \). If \( g_0, \ldots, g_r \) is another base of \( \mathcal{D}' \), there exists \( T \in \text{Aut}(\mathbb{P}^r(\mathbb{F})) \) such that \( \phi_1 := (g_0 : \cdots : g_r) = T \circ \phi_1 \); thus

\[
L_i^{g_0, \cdots, g_r}(P) = T(L_i^{f_0, \cdots, f_r}(P)) .
\]

We conclude then that \( L_i^{f_0, \cdots, f_r}(P) \) is uniquely determinated by \( \mathcal{D} \) up to projective equivalence.
Definition. $L_i(P) = L_i^{f_0, \ldots, f_r}(P)$ is called the $i$-th osculating space at $P$ (with respect to the base $\{f_0, \ldots, f_r\}$).

Clearly we have:

$$L_0(P) \subseteq \ldots \subseteq L_{r-1}(P).$$

Lemma 2.24. $L_i^{f_0, \ldots, f_r}(P)$ is an $i$-dimensional space generated by the vectors $(D_i^s \phi')(P)$, $s = 0, \ldots, i$, where $\phi' = (t^{v_P(E)} f_0 : \ldots : t^{v_P(E)} f_r)$.

Proof. From Lemma 1.10 and (2.8) we can assume that $f_0, \ldots, f_r$ is a $(D, P)$-base. Let $H_i$ be the hyperplane corresponding to $X_i = 0$, where $X_0, \ldots, X_r$ are homogeneous coordinates of $P^r$. Let $H : \sum_i a_i X_i = 0$ be a hyperplane. Then $v_P(\phi^s(H)) \geq j_{i+1}$ if and only if $a_0 = \ldots a_i = 0$, since $v_P(t^{v_P(E)} f_\ell) = j_\ell$ for each $\ell$. Thus

$$L_i^{f_0, \ldots, f_r}(P) = H_{i+1} \cap \ldots \cap H_r,$$

i.e., it has dimension $i$. In addition, it is generated by the vectors $(D_i^s \phi')(P)$ by the proof of Scholium 2.8

From the proof above we obtain:

Scholium 2.25. $H \supseteq L_i(P)$ if and only if $v_P(\phi^s(H)) \geq j_{i+1}$.

Remark 2.26. If $D$ has base points, the $i$-osculating spaces for $D$ are, by definition, those of $D^B$.

Definition. The 1-osculating (resp. $(r - 1)$-osculating) space at $P$ is called the tangent line (resp. osculating hyperplane) at $P$.

A consequence of Lemma 2.24 is the following.

Corollary 2.27. The osculating hyperplane at $P$ (with respect to the base $\{f_0, \ldots, f_r\}$) is given by the equation

$$\det \begin{pmatrix}
X_0 & \ldots & X_r \\
(D_i^0 g_0)(P) & \ldots & (D_i^0 g_r)(P) \\
\vdots & \vdots & \vdots \\
(D_i^{r-1} g_0)(P) & \ldots & (D_i^{r-1} g_r)(P)
\end{pmatrix} = 0,$$

where $g_\ell := t^{v_P(E)} f_\ell$, $\ell = 0, \ldots, r$.

2.5. Weierstrass points; Weierstrass semigroups II. In this sub-section we consider Weierstrass Point Theory for the canonical linear series $\mathcal{K} = \mathcal{K}^X$ on the curve $X$ of genus $g$. By Remark 1.21 we can assume $g \geq 2$. The special feature in the canonical case is the existence of a (numerical) semigroup, namely the Weierstrass semigroup $H(P)$ at $P \in \mathcal{X}$ (cf. Sect. 1.5) which is closely related to the $(\mathcal{K}, P)$-orders. We stress the following.
Definition.  (1) The Weierstrass points of the curve $\mathcal{X}$ is the set $W = W_{\mathcal{X}}$ of its $\mathcal{K}$-Weierstrass points; i.e., $W = \text{Supp}(R_\mathcal{K})$. The $\mathcal{K}$-weight of $P$ is called the Weierstrass weight $\omega_P$ of $P$; i.e., $\omega_P = v_P(R_\mathcal{K})$.

(2) We set $w_P := \sum_{i=0}^{g-1}(j_i^\mathcal{K}(P) - i)$; i.e., $w_P$ is the weight of the Weierstrass semigroup $H(P)$ at $P$.

(3) The curve $\mathcal{X}$ is called classical if it is classical with respect to the canonical linear series $\mathcal{K}$.

In particular, since $\mathcal{K}$ has dimension $g - 1$ and degree $2g - 2$, the number of Weierstrass points $P \in W$ counted with their weights $\omega_P$ equals

\[
(2.9) \quad \deg(R_\mathcal{K}) = \left( \sum_{i=0}^{g-1} \epsilon_i \right) (2g - 2) + g(2g - 2),
\]

where $\epsilon_0 < \ldots < \epsilon_{g-1}$ are the $\mathcal{K}$-orders. From Theorem 2.19(1) we have

$$\omega_P \geq \sum_{i=0}^{g-1} (j_i^\mathcal{K}(P) - \epsilon_i).$$

In general, $\omega_P > \sum_{i}(j_i^\mathcal{K}(P) - \epsilon_i)$ and $\omega_P \neq w_P$ (see Example 2.28); however, if either $p = 0$ or $p > 2g - 2$, then the curve is classical and $\omega_P = \sum_{i}(j_i^\mathcal{K}(P) - i) = w_P$ by Corollary 2.23; in this case the curve has $g(g^2 - 1)$ Weierstrass points (counted with their weights) by (2.9).

Example 2.28. (Hyperelliptic curves) Let $\mathcal{X}$ be hyperelliptic with $g^1_2 = |\text{div}_\infty(f)|$, $f \in R(\mathcal{X})$ of degree two. Note that $f$ is a separating variable since $g > 0$. We have $\mathcal{K} = \left( (g-1)\text{div}_\infty(f) \right)$, where $\mathcal{K}'$ is generated by $1, f, \ldots, f^{g-1}$. Then $W_{1,f,\ldots,f^{g-1},f} = 1$; i.e., $\mathcal{X}$ is classical.

The ramification divisor of $\mathcal{K}$ is thus

$$R_\mathcal{K} = \frac{g(g-1)}{2} \text{div}(df) + g(g-1)\text{div}_\infty(f),$$

so that $R_\mathcal{K} = g^{g-1}2R_f$ by Example 2.16. Note that $f$ has $\deg(R_f) = 2g + 2$ ramifications points (counted with multiplicity), and that $P \in \text{Supp}(R_f)$ if and only if $e_P = 2$; see Example 1.1. Therefore the following conditions are equivalent:

- $P \in W$;
- $P \in \text{Supp}(R_f)$;
- $e_P = 2$;
- $2 \in H(P)$;
- the $(\mathcal{K}, P)$-orders are $0, 2, \ldots, 2g - 2$. 
If \( P \notin \mathcal{W} \), then the \((\mathcal{K}, P)\)-orders are 0, 1, \ldots, \( g - 1 \); i.e., \( H(P) = \{ 0, g + 1, \ldots \} \). In particular, a hyperelliptic curve has only two types of Weierstrass semigroups.

If \( p = 0 \) or \( p > 2 \), and \( P \in \text{Supp}(R_f) \), then \( v_P(R_f) = 1 \) and hence \( \mathcal{X} \) has \( 2g + 2 \) Weierstrass points \( P \) such that \( \omega_P = g(g - 1)/2 \). In particular, here we have \( \omega_P = \sum_i (j_i^K - i) = w_P (\ast) \).

If \( p = 2 \), then \((\ast)\) is in general not true as the following example shows. Let \( \mathcal{X} \) be the non-singular model of the plane curve of equation

\[
y^2 + y = x^{q+1},
\]

over \( F \) of characteristic two, and where \( q = 2^a, a \geq 2 \). Then \( x \in F(\mathcal{X}) \) has degree two and so \( \mathcal{X} \) is hyperelliptic. There are two different points in \( \mathcal{X} \) over each \( a \in F \), since \( Y^2 + Y = a^{q+1} \) has two different solutions. Let \( P \) over \( x = \infty \). Then \( 2v_P(y) = -(q+1)e_P \) so that \( e_P = 2 \); hence there is just one point \( P_\infty \) over \( x = \infty \); i.e., \( \# \text{Supp}(R_x) = 1 \). In particular, \( P_\infty \) is the only Weierstrass point of \( \mathcal{X} \) and thus its weight is \( \omega_P = \deg(R^K) = g(g^2 - 1) > \sum_i (j_i^K - 1) = w_P = g(g - 1)/2 \) because \( g > 1 \) as we see below.

To compute the genus of \( \mathcal{X} \) we use the fact that \( P_\infty \) is the only ramified point for \( x \): We have \( 2g - 2 = \deg(\text{div}(dx)) = v_{P_\infty}(dx) = q - 2 \) and so \( g = q/2 > 1 \).

**Lemma 2.29.** Let \( \mathcal{X} \) be a classical curve of genus \( g \) such that \( \omega_P = w_P \) for each \( P \) (e.g. if \( p = 0 \) or \( p > 2g - 2 \)). Then

1. \( 2g + 2 \leq \# \mathcal{W} \leq g(g^2 - 1) \);
2. \( \# \mathcal{W} = 2g + 2 \) if and only if \( \mathcal{X} \) is hyperelliptic;
3. \( \# \mathcal{W} = g(g^2 - 1) \) if and only if \( \omega_P = 1 \) for any \( P \in \mathcal{X} \).

**Proof.** We have \( g(g^2 - 1) = \deg(R^K) = \sum_P w_P \leq \# \mathcal{W} g(g - 1)/2 \) by Corollary 1.26(1). This proves (1). (2) follows from Corollary 1.26(2)(3) and Example 2.28. (3) is trivial. \( \Box \)

**Lemma 2.30.** Let \((\tilde{n}_i : i \in \mathbb{N})\) be the Weierstrass semigroup at non-Weierstrass points. Then \( n_i(P) \leq \tilde{n}_i \) for each \( P \) and each \( i \).

**Proof.** Let \( i \) be the minimum positive integer such that \( n_i(P) > \tilde{n}_i \). Then \( i \geq 2 \) and \( n_{i-1}(P) \leq \tilde{n}_{i-1} \) so that \( n_{i-1}(P) \leq \tilde{n}_{i-1} < \tilde{n}_i < n_i(P) \). Now we have \( \tilde{n}_i = \ell_{\tilde{n}_i-1} \geq \ell_{\tilde{n}_i-1} \) by Corollary 2.10(1), where \( \ell_1 < \ell_2 < \ldots \) are the gaps at non-Weierstrass points. Since \( \ell_{\tilde{n}_i-1} \geq \tilde{n}_i + 1 \) we have a contradiction and the result follows. \( \square \)

**Lemma 2.31.** The largest \( \mathcal{K} \)-order \( \epsilon_{g-1} \) is less than \( \deg(\mathcal{K}) = 2g - 2 \).

**Proof.** (Garcia [27, p. 235]) Suppose \( \epsilon_{g-1} = 2g - 2 \). Then for \( P \notin \mathcal{W} \), \((2g - 2)P \) is a canonical divisor. In particular, \((2g - 2)P \sim (2g - 2)P_0 \) for \( P, P_0 \notin \mathcal{W} \) \((\ast)\). We consider the isogeny \( i : D \mapsto (2g - 2)D \) on the Jacobian variety \( \mathcal{J} \) associated to \( \mathcal{X} \), and the natural map \( \mathcal{X} \to \mathcal{J} \), \( P \mapsto [P - P_0] \). Note that \([P - P_0] = [Q - P_0] \) if and only \( P = Q \) since \( g > 0 \). Then \((\ast)\) says that there are infinitely many points in \( \mathcal{J} \) belonging to the kernel of \( i \), a contradiction since this kernel is finite [77, p. 62]. \( \square \)
Example 2.32. (The non-classical curve of genus 3) It is easy to see that the only semigroups of genus two are \(\{0, 3, 4, 5, \ldots\}\) and \(\{0, 2, 4, 5, \ldots\}\). Since a curve of genus two must have at least one Weierstrass points, then such a curve is hyperelliptic and hence classical.

Now let \(\mathcal{X}\) be a curve of genus three. We shall show a result due to Komiya [66]: \(\mathcal{X}\) is non-classical if and only if \(p = 3\) and \(\mathcal{X}\) is \(F\)-isomorphic to the non-singular plane curve of equation \(y^3 + y = x^4\). If \(\mathcal{X}\) is non-classical, then \(0 < p < 2g - 2 = 4\) by Corollary 2.23 so that \(p = 2, 3\). We have \(\epsilon_0 = 0, \epsilon_1 = 1\) and \(\epsilon_2 = 3\). Then \(p = 3\) by the 2-adic criterion. We have \(P \in \mathcal{W} \Leftrightarrow j^K_0(P) = 0, j^K_1(P) = 1, j^K_2(P) = 4 \Leftrightarrow H(P) = \{0, 3, 4, 6, \ldots\}\); then \(\omega_P = 1\) and \(\mathcal{X}\) has \(\text{deg}(K^P) = 28\) Weierstrass points (note that a classical curve of genus 3 has \(3 \times (3^2 - 1) = 24\) Weierstrass points counted with their weights). Let \(P_0 \in \mathcal{W}, x, y \in F(\mathcal{X})\) such that \(\text{div}_\infty(x) = 3P_0\) and \(\text{div}_\infty(y) = 4P_0\). We see that \(4P_0\) is a canonical divisor and so \(K = [4P_0]\). We also see that \(x\) is a separating variable of \(F(\mathcal{X})|\mathcal{F}\) so that \(W^{0,1,2}_{1.x;y;x} = D^2y = 0\) as \(\epsilon_2 > 2\). Now the eleven functions \(1, x, y, x^2, xy, y^2, x^3, x^2y, xy^2, x^4, y^3\) belong to \(L(12P_0)\) which has dimension 10. Therefore there is a non-trivial relation over \(F\) of type

\[
a_{00} + a_{10}x + a_{01}y + a_{20}x^2 + a_{11}xy + a_{02}y^2 + a_{30}x^3 + a_{21}x^2y + a_{12}xy^2 + a_{40}x^4 + a_{03}y^3 = 0.
\]

Since \(v_{P_0}(x^iy^j) < 12\) for \(3i + 4j < 12\) we must have \(a_{40} \neq 0\) and \(a_{03} \neq 0\). In particular we can assume \(a_{40} = 1\). Next we apply \(D^2_x\) to the equation above; using the fact that \(D^2_xy = 0\) we find:

\[
a_{20} + a_{11}Dxy + a_{02}(Dxy)^2 + a_{21}(y + 2xDy) + a_{12}(2xyDy + x(Dxy)^2) = 0.
\]

Let \(v_{P_0}(Dxy) = a\). Then the valuation at \(P_0\) of the functions

\[
1, Dxy, (Dxy)^2, y, xDy, xyDy, x(Dxy)^2
\]

are respectively

\[
0, a, 2a, -4, -3 + a, -7 + a, -3 + 2a;
\]

we see that they are pairwise different and hence \(a_{20} = a_{11} = a_{02} = a_{21} = a_{12} = 0\); i.e., we have

\[
a_{00} + a_{10}x + a_{01}y + a_{30}x^3 + x^4 + a_{03}y^3 = 0.
\]

By means of \(x \mapsto (x - a_{30})\) and \(y \mapsto -(a_{03})^{-1/3}y\) we can assume \(a_{30} = 0\) and \(a_{03} = -1\). Now as \([F(\mathcal{X}) : F(x)] = 3\) the above equation is irreducible and hence \(a_{01} \neq 0\) because \(x\) is a separating variable. Then by means of \(x \mapsto a_{01}^{3/8}x\) and \(y \mapsto a_{01}^{1/2}y\) we can assume \(a_{01} = 1\). So we have an equation of type

\[
y^3 + y = x^4 + a_{10}x + a_{00}.
\]

Finally let \(P_1\) be another Weierstrass point. Then \(4P_1 \sim 4P_0\) as both divisor are canonical. So we can choose \(y\) such that \(\text{div}(y) = 4P_1 - 4P_0\). Then \(4 = v_{P_1}(y) = v_{P_1}(x^4 + a_{10}x + a_{00})\) implies \(a_{00} = a_{10} = 0\).
Conversely if \( \mathcal{X} \) is defined by \( y^3 + y = x^4 \), we have that \( \mathcal{X} \) is a non-singular plane curve of genus three. Moreover there is just one point \( P_\infty \) over \( x = \infty \) and \( H(P_\infty) = \{0, 3, 4, 6, \ldots \} \). This implies that \( x \) is a separating variable and we have \( D_x^2y = 0 \); i.e., \( \mathcal{X} \) is non-classical.

Further examples of non-classical linear series can be found in Neeman [80]. Finally we mention that Weierstrass Point Theory on schemes was considered by Laksov and Thorup [72]; see the introduction there for further references.

3. Frobenius orders

Let \( \mathcal{X} \) be a curve defined over \( \mathbb{F}_q \), a finite field with \( q \) elements; i.e., \( \mathcal{X} \) is a curve over the algebraic closure \( \overline{\mathbb{F}}_q \) of \( \mathbb{F}_q \), equipped with the action of the Frobenius morphism \( \Phi_q \) relative to \( \mathbb{F}_q \). Let \( \mathcal{D} \cong \mathbb{P}(\mathcal{D}') \subseteq |E| \) be a base-point-free \( g_0^r \) on \( \mathcal{X} \). Assume that \( \mathcal{D} \) is also defined over \( \mathbb{F}_q \); i.e., for any \( D = \sum_P n_P P \in \mathcal{D} \), \( (\Phi_q)_*(D) := \sum_P n_P \Phi_q(P) = D \). Let \( \phi = (f_0 : \ldots : f_r) \) be a morphism over \( \mathbb{F}_q \) associated to \( \mathcal{D} \); i.e., its coordinates belong to \( \mathbb{F}_q(\mathcal{X}) \) and they form a \( \mathbb{F}_q \)-base of \( \mathcal{D}' \).

The starting point of Stöhr-Voloch’s approach to the Hasse-Weil bound is to look at points \( P \) of \( \mathcal{X} \) such that \( \phi(\mathbb{F}_q(P)) \) belongs to the osculating hyperplane \( L_{r-1}^{f_0,\ldots,f_r}(P) \) at \( P \). Then Corollary 2.27 leads to the consideration of rational functions of type

\[
V_{f_0,\ldots,f_r;x}^{\ell_0,\ldots,\ell_{r-1}} := \det \begin{pmatrix} f_0 \circ \Phi_q & \ldots & f_r \circ \Phi_q \\ D_x^{\ell_0} f_0 & \ldots & D_x^{\ell_r} f_r \\ \vdots & \vdots & \vdots \\ D_x^{\ell_{r-1}} f_0 & \ldots & D_x^{\ell_r} f_r \end{pmatrix},
\]

where \( x \) is a separating variable of \( \mathbb{F}_q(\mathcal{X})/\mathbb{F}_q \). We set

\[
\mathcal{B}(f_0, \ldots, f_r; x) := \{(m_0, \ldots, m_{r-1}) \in \mathbb{N}_0^r : m_0 < \ldots < m_{r-1}; V_{f_0,\ldots,f_r;x}^{m_0,\ldots,m_{r-1}} \neq 0\}.
\]

**Lemma 3.1.** Let \((m_0, \ldots, m_r) \in \mathcal{A}(f_0, \ldots, f_r; x)\) with \( m_0 = 0 \). Then there exists \( 0 < I \leq r \) such that \((m_0, \ldots, m_{I-1}, m_{I+1}, \ldots, m_r) \in \mathcal{B}(f_0, \ldots, f_r; x)\).

**Proof.** Let \( I \) be the smallest integer such that \( \phi \circ \Phi_q := (f_0 \circ \Phi_q, \ldots, f_r \circ \Phi_q) \) is a \( \mathbb{F}(\mathcal{X}) \)-linear combination of \( D_x^{m_0} \phi, \ldots, D_x^{m_r} \phi \). Since \( f_0, \ldots, f_r \) is a \( \mathbb{F}_q \)-base of \( \mathcal{D}' \), then \( I > 0 \) and the result follows. \( \square \)

Since the \( \mathcal{D} \)-order sequence \((\epsilon_0, \ldots, \epsilon_r)\) belongs to \( \mathcal{A}(f_0, \ldots, f_r; x) \) (cf. Proposition 2.11), \( \mathcal{B}(f_0, \ldots, f_r; x) \neq \emptyset \). Let

\[
\mathcal{V} := (\nu_0, \ldots, \nu_{r-1})
\]

be the minimum (in the lexicographic order) of \( \mathcal{B}(f_0, \ldots, f_r; x) \).

**Lemma 3.2.**

1. \( \nu_0 = 0 \);
2. For \( i = 1, \ldots, r - 1 \),
   \[
   \nu_i = \min\{s > \nu_{i-1} : \phi \circ \Phi_q, D_x^{m_0} \phi, \ldots, D_x^{m_{i-1}} \phi, D_x^{m_i} \phi \text{ are } \overline{\mathbb{F}}_q(\mathcal{X}) \text{-l.i.}\};
   \]
(3) Let \((m_0, \ldots, m_r) \in \mathcal{B}(f_0, \ldots, f_r; x)\). Then \(\nu_i \leq m_i\) for each \(i\).

Proof. Similar to the proofs of Lemma 2.9 and Corollary 2.10(1).

**Corollary 3.3.** There exists \(0 < I \leq r\) such that

\[
\nu_i = \begin{cases} 
\epsilon_i & \text{if } i < I, \\
\epsilon_i + 1 & \text{if } i \geq I.
\end{cases}
\]

**Proof.** From Proposition 2.11(3) and Lemma 3.1, there exists \(0 < I \leq r\) such that \((\epsilon_0, \ldots, \epsilon_I, \ldots, \epsilon_{l-1}, \ldots, \epsilon_r) \in \mathcal{B}(f_0, \ldots, f_r; x)\). Hence from Lemma 3.2, \(\nu_i \leq \epsilon_i\) for \(i < I\) and \(\nu_i = \epsilon_i + 1\) for \(i \geq I\). Since \(D_x^{\nu_0} \phi, \ldots, D_x^{\nu_{l-1}} \phi\) are \(\mathcal{F}_q(\mathcal{X})\)-linearly independent, the following is analogous to Proposition 2.11.

We remark the following computation regarding change of basis. Let \(g_i = \sum_{a_{ij}} a_{ij} f_j\) with \((a_{ij}) \in M_{r+1}(\mathcal{F}_q)\). Then

\[
(3.1) \quad \det \begin{pmatrix}
\tilde{g}_0 & \cdots & \tilde{g}_r \\
D_x^{\nu_0} g_0 & \cdots & D_x^{\nu_0} g_r \\
\vdots & \ddots & \vdots \\
D_x^{\nu_{l-1}} g_0 & \cdots & D_x^{\nu_{l-1}} g_r
\end{pmatrix} = \det(a_{ij}) V_{f_0, \ldots, f_r; x}^{(\nu_0, \ldots, \nu_{l-1})},
\]

where \(\tilde{g}_j = \sum_i a_{ij} f_i \circ \Phi_q\). The following is analogous to Proposition 2.11.

**Proposition 3.4.**

1. If \(g_i = \sum_j a_{ij} f_j\) with \((a_{ij}) \in M_{r+1}(\mathcal{F}_q)\), then

\[
V_{\nu_0, \ldots, \nu_{l-1}; x}^{(\nu_0, \ldots, \nu_{l-1})} = \det((a_{ij})) V_{f_0, \ldots, f_r; x}^{(\nu_0, \ldots, \nu_{l-1})};
\]

2. If \(f \in \mathcal{F}_q(\mathcal{X})\), then

\[
V_{f_0, \ldots, f_r; x}^{(\nu_0, \ldots, \nu_{l-1})} = f^{q-r} V_{f_0, \ldots, f_r; x}^{(\nu_0, \ldots, \nu_{l-1})};
\]

3. Let \(y\) be any separating variable of \(\mathcal{F}_q(\mathcal{X})|\mathcal{F}_q\). Then

\[
V_{f_0, \ldots, f_r; y}^{(\nu_0, \ldots, \nu_{l-1})} = (D_y x)^{\sum \nu_i} V_{f_0, \ldots, f_r; x}^{(\nu_0, \ldots, \nu_{l-1})}.
\]

Proof. (1) follows from (3.1) taking into consideration that \(a_{ij}^q = a_{ij}\). (2) and (3) follow as in Proposition 2.11.

Now we show that \(V\) just depend on \(D\) and \(q\). Let \(\{f'_0, \ldots, f'_r\} \subseteq \mathcal{F}_q(\mathcal{X})\) be another \(\mathcal{F}_q\)-basis of \(\mathcal{D}'\) and \(y\) another separating variable of \(\mathcal{F}_q(\mathcal{X})|\mathcal{F}_q\). From part (1) above, \(V\) is the minimum for \(\mathcal{B}(f'_0, \ldots, f'_r; x)\) and from part (3) it is also the minimum for \(\mathcal{B}(f'_0, \ldots, f'_r; y)\).
**Definition.** \(\mathcal{V} = (\nu_0, \ldots, \nu_{r-1})\) is called the \(\mathbb{F}_q\)-Frobenius orders of \(\mathcal{D}\). If \(\nu_i = i\) for each \(i\), \(\mathcal{D}\) is called \(\mathbb{F}_q\)-Frobenius classical.

Now let \(P \in \mathcal{X}\). We have that \(v_P(E) = -\min(v_P(f_0), \ldots, v_P(f_r))\) because \(\mathcal{D}\) is base-point-free, cf. Lemma 1.4. In addition, the rational functions \(g_i := t^{v_P(E)} f_i\) are regular at \(P\) for each \(i\), where \(t\) is a local parameter at \(P\). Let \(\{f_0', \ldots, f_r'\}\) and \(y\) be as above. Let \(f_i' = \sum_j a_{ij} f_j\), \(a_{ij} \in \mathbb{F}_q\). Applying Proposition 3.4 we have

\[
V_{f_0' \ldots f_r'; y}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}} = \det(a_{ij}) V_{f_0 \ldots f_r; y}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}} = \det(a_{ij})(D_q^t)^{\nu_i} V_{f_0 \ldots f_r; t}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}} = \det(a_{ij})(D_q^t)^{\nu_i} t^{-(q + r)v_P(E)} V_{f_0 \ldots f_r; t}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}},
\]

i.e.,

\[
(3.2) \quad V_{f_0' \ldots f_r'; y}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}} \left(\frac{dy}{dt}\right)^{\nu_i} t^{-(q + r)v_P(E)} = \det(a_{ij}) V_{f_0 \ldots f_r; t}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}}. \]

Therefore the divisor

\[
S = S_{P,q} := \text{div}(V_{f_0' \ldots f_r'; y}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}}) + \left(\sum_{i=0}^{r-1} \nu_i\right)\text{div}(dy) + (q + r)E,
\]

just depend on \(\mathcal{D}\) and \(q\) and locally at \(P\) is given by (3.2).

**Definition.** \(S\) is called the \(\mathbb{F}_q\)-Frobenius divisor of \(\mathcal{D}\).

The divisor \(S\) is effective because, as we already noticed, each \(g_\ell\) is regular at \(P\). Note that

\[
\deg(S) = \left(\sum_{i=0}^{r-1} \nu_i\right)(2g - 2) + (q + r)d.
\]

Next we study \(v_P(S)\) by means of (3.2); i.e. we study

\[
v_P(S) = v_P(V_{f_0' \ldots f_r'; t}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}}).
\]

We consider two cases according as \(P\) is \(\mathbb{F}_q\)-rational or not.

**Case I:** \(P \in \mathcal{X}(\mathbb{F}_q)\). Here we can assume that \(f_0, \ldots, f_r\) is a \((\mathcal{D}, P)\)-base; i.e. \(v_P(g_\ell) = j_\ell\) for \(\ell = 0, \ldots, r\). By Proposition 3.4(2)

\[
v_P(S) = v_P(g_0^{q + r} V_{h_0' \ldots h_r'; t}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}}) = v_P(V_{h_0' \ldots h_r'; t}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}}),
\]

where \(h_\ell := g_\ell / g_0\). Note that \(h_0 = 1\) and that \(v_P(h_\ell) = j_\ell\). In particular,

\[
(3.3) \quad V_{h_0' \ldots h_r'; t}^{\nu_{\nu_0} \ldots \nu_{\nu_{r-1}}} = \det\left(\begin{array}{ccc}
h_1 - h_0 & \ldots & h_r - h_0 \\
D_t^{v_1} h_1 & \ldots & D_t^{v_1} h_r \\
\vdots & \ddots & \vdots \\
D_t^{v_{r-1}} h_1 & \ldots & D_t^{v_{r-1}} h_r
\end{array}\right),
\]
and we can made similar computations as in the proof of Lemma 2.7: Expand \( h_\ell \) at \( P \),
\[
h_\ell = \sum_{s=0}^{\infty} c_\ell^s t^s,
\]
set \( C := \prod_{\ell=1}^{r} c_\ell^\ell \); then

\[
V_{h_0, \ldots, h_{r}; t}^{i_0, \ldots, i_{r-1}} = C \det\left( \frac{j_\ell^{i_\ell}}{\nu_i} \right) t^{\sum_{i=1}^{r}(i_i - \nu_{i-1})} + \ldots,
\]

where \( i = 0, \ldots, r - 1; \ell = 1, \ldots, r \) in the matrix above involving the binomial operator.

Now \( v_P(S) \) can be estimated via this local expansion.

**Case II:** \( P \not\in \mathcal{X}(\mathbb{F}_q) \). Let \( h_0, \ldots, h_r \) be a \((\mathcal{D}, P)\)-base. Then there exists \((a_{ij}) \in M_{r+1}(\mathbb{F}_q)\) such that \( h'_\ell := t^{v_P(E)} h_i = \sum_j a_{ij} g_j \). Then from (3.1)
\[
v_P(S) = v_P(\sum_{i=0}^{r} (-1)^i h'_i d_i),
\]
where the \( d_i \)'s are the determinants obtained by Cramer’s rule. Clearly \( v_P(h'_i) \geq 0 \) and so
\[
v_P(S) \geq \min\{v_P(d_0), \ldots, v_P(d_r)\}.
\]
Once again we can expand each \( d_i \) at \( P \) as in the proof of Lemma 2.7: Let \( M := ((j_\ell^{i_\ell})_{k=0, \ldots, r; \ell=0, \ldots, r}) \) and let \( M_i \) be the matrix obtained from \( M \) by deleting the \( i \)-th column. Then
\[
d_i = C_i \det(M_i) t^{\sum_{k=0}^{r} j_k - \sum_{k=0}^{r-1} \nu_k} + \ldots,
\]
where \( C_i \in \mathbb{F}_q^* \). Thus (3.4) and (3.5) imply the following.

**Proposition 3.5.** (1) For \( P \in \mathcal{X}(\mathbb{F}_q) \), \( v_P(S) \geq \sum_{i=1}^{r}(j_i(P) - \nu_{i-1}) \); equality holds if and only if \( \det((j_\ell^{i_\ell}(P))_{i=0, \ldots, r-1; \ell=1, \ldots, r}) \equiv 0 \) (mod \( p \));

(2) For \( P \not\in \mathcal{X}(\mathbb{F}_q) \), \( v_P(S) \geq \sum_{i=1}^{r}(j_i(P) - \nu_i) \); if \( \det((j_\ell^{i_\ell}(P))_{i, \ell=0, \ldots, r}) \equiv 0 \) (mod \( p \)), then the stric inequality holds.

**Proposition 3.6.** Let \( \nu \) be a \( \mathbb{F}_q \)-Frobenius order such that \( \nu < q \). Let \( \mu \) an integer such that \( \binom{\nu}{\mu} \not\equiv 0 \) (mod \( p \)). Then \( \mu \) is also an \( \mathbb{F}_q \)-Frobenius order. In particular, if \( \nu_i < p \) then \( (\nu_0, \ldots, \nu_i) = (0, \ldots, i) \).

**Proof.** Let \( \nu = \nu_i \). For \( j \leq i \), we have \( D_\ell^\nu(f^j) = 0 \) by Remark 2.5. So \( \nu_0, \ldots, \nu_i \) are the first \( i + 1 \) orders of the morphism \((h_1 - h_0^2 ; \ldots ; h_r - h_0^2)\), where \( h_1, \ldots, h_r \) are as in (3.3). Then the result follows from the \( p \)-adic criterion (Lemma 2.21).

Next we study relations between the \( \mathbb{F}_q \)-Frobenius orders and \((\mathcal{D}, P)\)-orders at \( \mathbb{F}_q \)-rational points \( P \).

**Proposition 3.7.** Let \( P \in \mathcal{X}(\mathbb{F}_q) \) and \( m_0 < \ldots < m_{r-1} \) be a sequence of non-negative integers such that \( \det((j_\ell^{i_\ell}(P)-j_\ell^{i_\ell}(P))_{i=0, \ldots, r-1; \ell=1, \ldots, r}) \not\equiv 0 \) (mod \( p \)). Then \( \nu_i \leq m_i \) for each \( i \).
Proof. Set \( j_i = j_i(P) \) and let \( \phi := (1 : x^{j_2-j_1} : \ldots : x^{j_r-j_1}) \), where \( x \) is a separating variable of \( \overline{F}_{q}(\mathcal{X})|F_{q} \). Let \( \eta_0 < \ldots < \eta_{r-1} \) be the orders of \( \phi \). Then \( \eta_i \leq m_i \) for each \( i \) by (2.6), hypothesis and Corollary 2.10(1). Then, as \( \phi = (x^{j_1} : \ldots : x^{j_r}) \), \( \det((j^{i}_{j_i})) \neq 0 \pmod p \), and the result follows from (3.4).

Remark 3.8. From the proof above follows that the best election of the \( m_i \)'s in Proposition 3.7 are the orders of the morphism \( \phi = (x^{j_1(P)} : \ldots : x^{j_r(P)}) \).

**Corollary 3.9.** Let \( P \in \mathcal{X}(F_q) \).

1. \( v_i \leq j_{i+1}(P) - j_i(P) \) for \( i = 0, \ldots, r-1 \), and so \( v_P(S) \geq r j_1(P) \);

2. Suppose \( a := \prod_{1 \leq i < \ell \leq r} (j_{\ell}(P) - j_i(P))/(\ell - i) \neq 0 \pmod p \). Then \( D \) is \( F_q \)-Frobenius classical and \( v_P(S) = r + \sum_{i=1}^{r} (j_i(P) - i) \).

**Proof.** Note that \( a = \det((j^{i}_{j_i}(P)))_{i=0,\ldots,r-1; \ell=1,\ldots,r} \). Then (1) (resp. (2)) follows from Proposition 3.7 with \( m_i = j_{i+1}(P) - j_i(P) \) (resp. from the proof of Proposition 3.7 with \( m_i = i \), and Proposition 3.5(1)).

**Remark 3.10.** The criterion of Corollary 3.9(2) is satisfied if \( j_\ell(P) - j_i(P) \neq 0 \pmod p \) for \( 1 \leq i < \ell \leq r \). In particular, the criterion is satisfied if \( p \geq j_r(P) \).

**Corollary 3.11.**

1. If \( P \in \mathcal{X}(F_q) \) and \( \det((j^{i}_{j_i}(P)))_{j=0,\ldots,r-1; \ell=1,\ldots,r} \neq 0 \pmod p \), then \( v_i = \epsilon_i \) for \( i = 0, \ldots, r-1 \);

2. If \( D \) is not \( F_q \)-Frobenius classical, then \( j_r(P) > r \) for any \( P \in \mathcal{X}(F_q) \);

3. If \( (\nu_0, \ldots, \nu_{r-1}) \neq (\epsilon_0, \ldots, \epsilon_{r-1}) \), then \( \mathcal{X}(F_q) \subseteq \text{Supp}(R) \).

**Proof.** (1) follows from Proposition 3.7 with \( m_i = \epsilon_i \).

(2) If there exists \( P \in \mathcal{X}(F_q) \) such that \( j_r(P) = r \), then \( v_i = i \) for each \( i \) by Corollary 3.9(1).

(3) Suppose that there exists \( P \in \mathcal{X}(F_q) \setminus \text{Supp}(R) \). Then \( j_i(P) = \epsilon_i \) for each \( i \) and hence \( v_i \leq \epsilon_{i+1} - \epsilon_1 \) by Corollary 3.9(1); i.e. \( v_i = \epsilon_i \) for each \( i \), a contradiction.

**Remark 3.12.** If we choose \( i \) such that \( \mathcal{X}(F_q') \not\subseteq \text{Supp}(R) \), then from Corollary 3.11(3) we see that the \( F_q \)-order sequence of \( D \) coincide with \((\epsilon_0, \ldots, \epsilon_{r-1})\).

**Theorem 3.13.** Let \( \mathcal{X} \) be a curve defined over \( F_q \) that admits a base-point-free linear series \( D = g_d' \) defined over \( F_q \). Let \( \nu_0 < \ldots < \nu_{r-1} \) be the \( F_q \)-Frobenius orders of \( D \). Then

\[
\#\mathcal{X}(F_q) \leq \frac{\sum_{i=0}^{r-1} \nu_i(2g-2) + (q + r)d}{r}. 
\]

**Proof.** Let \( S \) be the \( F_q \)-Frobenius divisor of \( D \). Then \( v_P(S) \geq r \) for each \( P \in \mathcal{X}(F_q) \) by Corollary 3.9(1), and so \( \#\mathcal{X}(F_q) \leq \deg(S)/r \).

**Example 3.14.** (The Hermitian curve over \( F_q \)) We are looking for a curve \( \mathcal{X} \) of genus 3 defined over \( F_q \) such that \( \#\mathcal{X}(F_q) > 2q + 8 \). Let \( \epsilon_0 = 0 < \epsilon_1 = 1 < \epsilon_2 \) (resp. \( \nu_0 = 0 < \nu_1 \)) be the canonical orders (resp. canonical \( F_q \)-orders).
Claim. \( \mathcal{X} \) is non-classical; i.e., \( \epsilon_2 > 2 \).

Indeed, if \( \epsilon_2 = 2 \), then \( \nu_1 \leq 2 \) by Corollary 3.3 and Theorem 3.13 gives \( \#\mathcal{X}(\mathbb{F}_q) \leq 2q + 8 \).

Therefore from Example 2.32 we conclude that \( q \) is a power of three, \( \epsilon_2 = 3 \), and that \( \mathcal{X} \) is given by \( y^3 + a_{01}y = x^4 \), with \( a_{01} \in \mathbb{F}_q \) (notice that the change of coordinates involving \( a_{01} \) in Example 2.32 is not defined over \( \mathbb{F}_q \)). Moreover, the proof above also shows that \( \nu_1 > 2 \); i.e \( \nu_1 = 3 \).

Claim. \( q = 9 \) and \( \mathcal{X} \) is \( \mathbb{F}_9 \)-isomorphism to the Hermitian curve \( y^3 + y = x^4 \). In addition, \( \mathcal{X}(\mathbb{F}_9) = \mathcal{W} \) (so that \( \#\mathcal{X}(\mathbb{F}_9) = 28 > 2 \times 9 + 8 \)).

Let \( x \) and \( y \) be as in Example 2.32. Then \( V_{1,x,y:x}^{0,1} = 0 \) or equivalently \( y - y^q = (x - x^q)D_2y \) \((*)\). Then taking valuation at \( P \) we have \( -4q = -3q - 9 \) so that \( q = 9 \). Moreover from \((*)\) and the equation defining \( \mathcal{X} \) we have \((1-a_{01}^3)y^3+(a_{10}-1)y^q = 0 \) so that \( a_{01} = 1 \). That \( \mathcal{X}(\mathbb{F}_9) \subseteq \mathcal{W} \) follows from Corollary 3.11(3) and equality holds since \( \#\mathcal{X}(\mathbb{F}_9) = 28 \) (see Sect. 4.2).

Finally, observe that \( \#\mathcal{X}(\mathbb{F}_9) \) attains the bound in Theorem 3.13.

**Example 3.15.** (The Hermitian curve, I) Let \( \ell \) be a power of a prime and \( \mathcal{H} \) the plane curve of equation

\[
Y^\ell Z + YZ^\ell = X^{\ell+1}.
\]

It is easy to see that \( \mathcal{H} \) is non-singular so that it has genus \( g = \ell(\ell - 1)/2 \) by Remark 1.8.

Claim. \( \#\mathcal{H}(\mathbb{F}_\ell) = \ell^3 + 1 \).

Indeed, we have \( \mathcal{H} \cap (Z = 0) = \{(0 : 1 : 0)\}; \) in \( Z \neq 0 \) we look for points \((x : y : 1)\) such that \( y^\ell + y = x^{\ell+1} \). It follows that \( x \in \mathbb{F}_\ell \Rightarrow y \in \mathbb{F}_\ell \) and since \( Y^\ell + Y = x^{\ell+1} \) has \( \ell \) different solutions for \( Y \) we conclude that there are \( \ell^3 \) such \((x : y : 1)\) points.

Now over \( x := X/Z = \infty \) there is just one point say \( P_\infty \) such that \( H(P_\infty) \subseteq (\ell, \ell+1) \). Since \( \#(\mathbb{N} \setminus (\ell, \ell + 1)) = \ell(\ell - 1)/2 = g \), \( H(P_\infty) = (\ell, \ell+1) \). Next we consider \( \mathcal{D} := |((\ell + 1)P_\infty)| \) which is a \( g_{\ell+1}^2 \) base-point-free on \( \mathcal{H} \). Since \( L((\ell + 1)P_\infty) = \langle 1, x, y \rangle \), where \( y^\ell + y = x^{\ell+1} \) we see that \( \mathcal{D} \) is just the linear series cut out by lines on \( \mathcal{H} \). Let \( \epsilon_0 = 0, \epsilon_1 = 1, \epsilon_2 \) (resp. \( \nu_0 = 0, \nu_1 \in \{1, \epsilon_2\} \)) denote the \( \mathcal{D} \)-orders (resp. \( \mathbb{F}_\ell \)-Frobenius orders) of \( \mathcal{H} \).

Claim. \( j_2(P) = \ell + 1 \quad \text{if} \quad P \in \mathcal{H}(\mathbb{F}_\ell) \); \( j_2(P) = \ell \) otherwise.

In fact, \( 2\#\mathcal{H}(\mathbb{F}_\ell) \leq \nu_1(2g - 2) + (\ell^2 + 2)(\ell + 1) \) by Theorem 3.13 so that \( \nu_1 \geq \ell \). Then \( \ell \leq \nu_1 = \epsilon_2 \leq \ell + 1 \) and so \( \ell = \nu_1 = \epsilon_2 \) by Lemma 2.21 \( (p \text{-adic criterion}) \). That \( j_2(P) = \ell + 1 \) whenever \( P \in \mathcal{H}(\mathbb{F}_\ell) \) follows from Corollary 3.9(1) and part (1). In particular for such points \( P \), \( v_P(R) = 1 \). Now we have \( \deg(R^P) = \ell^3 + 1 \) and therefore \( j_2(P) = \ell \) for \( P \not\in \mathcal{X}(\mathbb{F}_\ell) \).
We can write a direct proof of part (2) as follows. Let \( a, b \in \overline{F}_\ell \) such that \( b^\ell + b = a^{\ell+1} \). It is easy to see that \((x-a)\) is a local parameter at \((a : b : 1) \in \mathcal{H}\) so that \((y-b) = a^\ell(x-a) + (a-a^\ell)(x-a)^\ell + (x-a)^{\ell+1} + \ldots\). Let

\[
f := (y-b) - a^\ell(x-a)\.
\]

Then

\[
\text{div}(f) = \ell(a : b : 1) + (a^{\ell^2} : b^{\ell^2} : 1) - (\ell + 1)P_{\infty}
\]

and part (2) follows.

Further arithmetical and geometrical properties of Frobenius orders can be read in Garcia-Homma [29]. From that paper we mention the following.

**Lemma 3.16.** ([29, Cor. 3]) Let \( \mathcal{V} = \mathcal{E} \setminus \{\epsilon_1\} \) and suppose that \( I < r \). Then \( \text{char}(F_q) \) divides \( \epsilon_{\ell+1} \).

### 4. Optimal curves

Let \( \mathcal{X} \) be a curve defined over \( F_q \) of genus \( g \). To study quantitative results on the number of \( F_q \)-rational points of \( \mathcal{X} \) it is convenient to form a formal power series, the so-called **Zeta Function** of \( \mathcal{X} \) relative to \( F_q \):

\[
Z_{\mathcal{X},q}(t) := \exp\left(\sum_{i=1}^{\infty} \frac{\# \mathcal{X}(F_q^i)}{i} t^i \right).
\]

By the Riemann-Roch theorem there exists a polynomial \( P(t) \) of degree \( 2g \) with integer coefficients, such that (see e.g. [78, Thm. 3.2], [96, Thm. V.1.15])

\[
(4.1) \quad Z_{\mathcal{X},q}(t) = \frac{P(t)}{(1-t)(1-qt)}.
\]

**Remark 4.1.** ([96, Thm. V.1.15])

(i) Let \( P(t) = \sum_{i=0}^{2g} a_i t^i \). Then \( a_0 = 1, a_{2g} = q^g \), and \( a_{2g-i} = q^{g-i} a_i \) for \( i = 0, \ldots, g \).

(ii) Set

\[
h(t) = h_{\mathcal{X},q}(t) := t^{2g} P(t^{-1});
\]

then the \( 2g \) roots (counted with multiplicity) \( \alpha_1, \ldots, \alpha_{2g} \) of \( h(t) \) can be arranged in such a way that \( \alpha_j \alpha_{g+j} = q \) for \( j = 1, \ldots, g \). Note that \( a_1 = -\sum_{j=1}^{2g} \alpha_j \).

Now (4.1) implies \( \# \mathcal{X}(F_q) = q + 1 + a_1 \) and hence that

\[
\# \mathcal{X}(F_q) = q + 1 - \sum_{j=1}^{2g} \alpha_j,
\]
by Remark 4.1(ii). Furthermore [96, Cor. V.1.16],

$$\# \mathcal{X}(\mathbb{F}_{q^r}) = q^r + 1 - \sum_{j=1}^{2g} \alpha_j^r.$$ 

By analogy with the Riemann hypothesis E. Artin conjectured that the absolute value of each $\alpha_i$ equals $\sqrt{q}$. This result was showed by Hasse for $g = 1$ and for A. Weil for arbitrary $g$ [108] (see also [99, Cor. 2.14], [78], [96, Thm. V.2.3]). In particular, we obtain the Hasse-Weil bound on the number of $\mathbb{F}_{q^r}$-rational points of $\mathcal{X}$, namely

$$|\# \mathcal{X}(\mathbb{F}_q) - (q + 1)| \leq 2\sqrt{q}.$$ 

If $\mathcal{X}$ attains the upper bound above, it is called $\mathbb{F}_q$-maximal; in this case $q$ must be a square.

**Lemma 4.2.** Let $q = \ell^2$. The following statements are equivalent:

1. $\mathcal{X}$ is $\mathbb{F}_{\ell^2}$-maximal;
2. $\alpha_i = -\ell$ for $i = 1, \ldots, 2g$;
3. $h_{\mathcal{X}, \ell^2}(t) = (t + \ell)^{2g}$.

If any of these conditions hold and $\mathcal{X}$ is defined over $\mathbb{F}_\ell$, then

$$\# \mathcal{X}(\mathbb{F}_{\ell^2}) = \begin{cases} \ell^2 + 1 & \text{if } i \equiv 1 \pmod{4}, \\ \ell^2 + 1 + 2\sqrt{\ell} & \text{if } i \equiv 2 \pmod{4}, \\ \ell^2 + 1 - 2\sqrt{\ell} & \text{if } i \equiv 0 \pmod{4}. \end{cases}$$ 

**Proof.** $\mathcal{X}$ is $\mathbb{F}_{\ell^2}$-maximal if and only if $\sum_{i=1}^{2g} \alpha_i = \sum_{i=1}^{2g} (\alpha_i + \bar{\alpha}_i) = -2\ell g$. By the Riemann-hypothesis, this is the case if and only if $\alpha_i = -\ell$ for each $i$ and the equivalences follow. Now we show the formulae on the number of rational points. Let $\# \mathcal{X}(\mathbb{F}_\ell) = \ell + 1 - \sum_{j=1}^{2g} \beta_j$. Then $\beta_j^2 = -\ell$ for each $j$ so that $\beta_j^2 + \beta_j = 0$ for $i \equiv 1 \pmod{2}$; i.e., $\# \mathcal{X}(\mathbb{F}_{\ell^2}) = \ell^2 + 1$. If $i \equiv 2 \pmod{4}$, $\beta_j^2 = -\sqrt{\ell}$ and follows the formula for such $i$’s. Finally, if $i \equiv 0 \pmod{4}$, $\beta_j = \sqrt{\ell}$ and the proof is complete. 

**Corollary 4.3.** (Ihara [58]) If $\mathcal{X}$ is $\mathbb{F}_{\ell^2}$-maximal, then $g \leq \ell(\ell - 1)/2$.

**Proof.** We have $\mathcal{X}(\mathbb{F}_{\ell^2}) \subseteq \mathcal{X}(\mathbb{F}_{\ell^4})$. Then from the lemma above, $\ell^2 + 2\ell g \leq \ell^4 + 1 - 2\ell^2 g$, and the result follows. 

**Example 4.4.** (The Hermitian curve, II) The curve $\mathcal{H}$ in Example 3.15 has genus $\ell(\ell - 1)/2$ and $\ell^3 + 1$ $\mathbb{F}_{\ell^2}$-rational points. Hence it is $\mathbb{F}_{\ell^2}$-maximal and attains the bound in Corollary 4.3.

This curve is called the Hermitian curve and it is the most fancy example of a maximal curve. By Lachaud [70, Prop. 6] any curve $\mathbb{F}_{\ell^2}$-covered by a $\mathbb{F}_{\ell^2}$-maximal curve is also $\mathbb{F}_{\ell^2}$-maximal. Then one obtains further examples of $\mathbb{F}_{\ell^2}$-maximal curves by e.g. considering
suitable quotient curves $\mathcal{H}/G$, where $G$ a subgroup of $\text{Aut}_{F_{\ell^2}}(\mathcal{H})$; see Garcia-Stichtenoth-Xing [31], and [14], [15]. As a matter of fact, all the known examples of $F_{\ell^2}$-maximal curves arise in this way.

**Problem 4.5.** Is any $F_{\ell^2}$-maximal curve $F_{\ell^2}$-covered by $\mathcal{H}$?

Further properties of maximal curves can be found in [24], [26], [67], [68] and the references therein.

If $q$ is not a square, the Hasse-Weil bound was improved by Serre [93, Thm. 1] as follows (see also [96, Thm. V.3.1])

$$\left|\#\mathcal{X}(F_q) - (q + 1)\right| \leq [2\sqrt{q}]g.$$  

**Lemma 4.6.** The following statements are equivalent:

1. $\mathcal{X}$ is maximal with respect to Serre’s bound;
2. $\alpha_i + \bar{\alpha}_i = -[2\sqrt{q}]$ for $i = 1, \ldots, g$;
3. $h_{\mathcal{X};q}(t) = (t^2 + [2\sqrt{q}]t + q)^g$.

**Proof.** $\mathcal{X}$ is maximal with respect to Serre’s bound if and only if $\sum_{i=1}^{g}(\alpha + \bar{\alpha}_i) = -[2\sqrt{q}]g$ if and only if $\alpha_i + \bar{\alpha}_i = -[2\sqrt{q}]$. Now, as we can assume $\alpha_i\bar{\alpha}_i = q$ by Remark 4.1(ii) so that $h_{\mathcal{X};q}(t) = \prod_{i=1}^{g}(t - \alpha_i)(t - \bar{\alpha}_i)$, the result follows. □

**Corollary 4.7.** We have $g \leq (q^2 - q)/([2\sqrt{q}]^2 + [2\sqrt{q}] - 2q)$ whenever $\mathcal{X}$ is maximal with respect to Serre’s bound.

**Proof.** As in the proof of Corollary 4.3 we use $\mathcal{X}(F_q) \subseteq \mathcal{X}(F_{\ell^2})$. We have $\alpha_i + \bar{\alpha}_i = -[2\sqrt{q}]$ and $\alpha_i\bar{\alpha}_i = q$ so that $\alpha_i^2 + \bar{\alpha}_i^2 = [2\sqrt{q}]^2 - 2q$; hence

$$\#\mathcal{X}(F_q) = q + 1 + [2\sqrt{q}] \leq \#\mathcal{X}(F_{\ell^2}) = q^2 + 1 - ([2\sqrt{q}]^2 - 2q)g,$$

and the result follows. □

**Remark 4.8.** The proofs of the following statements are similar to the proofs of Lemmas 4.2 and 4.6.

(i) A curve $\mathcal{X}$ defined over $F_{\ell^2}$ is $F_{\ell^2}$-minimal; i.e., $\#\mathcal{X}(F_{\ell^2}) = \ell^2 + 1 - 2\ell g$ if and only if $h_{\mathcal{X};\ell^2}(t) = (t - \ell)^{2g}$.

(ii) A curve $\mathcal{X}$ defined over $F_q$ is minimal with respect to Serre’s bound; i.e., $\#\mathcal{X}(F_q) = q + 1 - [2\sqrt{q}]g$ if and only if $h_{\mathcal{X};q}(t) = (t^2 - [2\sqrt{q}]t + q)^g$.

**Example 4.9.** (The Klein quartic) Let $\mathcal{X}$ be the plane curve over $F$ defined by

$$X^3Y + Y^3Z + Z^3X = 0.$$  

It is easy to see that $\mathcal{X}$ is non-singular if and only if $\text{char}(F) \neq 7$; in this case $\mathcal{X}$ has genus 3. This curve was considered by many authors since the time of Klein who showed that $\text{Aut}(\mathcal{X})$ reaches the Hurwitz bound for the number of automorphism of curves of genus 3 whenever $\text{char}(F) = 0$. A connection with the Fano plane was noticed by Pellikaan [84].
Claim. $\mathcal{X}$ defined over $\mathbb{F}_8$ reaches the Serre’s bound; i.e., $\#\mathcal{X}(\mathbb{F}_8) = 1 + 9 + [2\sqrt{8}]3 = 24$.

To see this we first notice that $(1 : 0 : 0), (0 : 1 : 0), (0 : 0 : 1)$ are $\mathbb{F}_8$-rational points (this is true for any field where $\mathcal{X}$ is defined). Now (cf. [84, p. 10]) we look for $(x : y : 1) \in \mathcal{X}$ such that $x \neq 0, y \neq 0$ and such that $x^7 = 1$. We have

$$0 = x^3 y + y^3 + x = x^3 y + x^7 y^3 + x = x(x^2 y + (x^2 y)^3 + 1);$$

i.e., $t^3 + t + 1 = 0$ (*). Conversely, it is easy to see that equation (*) is irreducible over $\mathbb{F}_2$ and hence its three roots are in $\mathbb{F}_8$. Then once $x \in \mathbb{F}_8^*$ we have $y \in \mathbb{F}_8^*$ by (*). Therefore we have 21 such points $(x : y : 1)$ and the claim follows.

Then $h_{\mathcal{X},8}(t) = (t^2 + 5t + 8)^3$ by Lemma 4.6.

Claim. $h_{\mathcal{X},2}(t) = t^6 + 5t^3 + 8$; in particular $\#\mathcal{X}(\mathbb{F}_2) = 3$.

Let $h_{\mathcal{X},2}(t) = \prod_{i=1}^{3}(t - \beta_i)(t - \bar{\beta}_i)$. Then $\beta_3 + \bar{\beta}_3 = -5$ (cf. Lemma 4.6) so that $\beta_3$ and $\bar{\beta}_3$ are roots of $T^2 + 5T + 8 = 0$; then $h_{\mathcal{X},2}(t) = t^6 + 5t^3 + 8$ so that $\#\mathcal{X}(\mathbb{F}_2) = 2 + 1 - 0 = 3$.

Finally, we mention that $\mathcal{X}$ is $\mathbf{F}_2$-maximal if and only if either $\ell = p^{6v+1}$ and $p \equiv 6 \pmod{7}$, or $\ell = p^{6v+3}$ and $p \equiv 3, 5, 6 \pmod{7}$, or $\ell = p^{6v+5}$ and $p \equiv 6 \pmod{7}$; see [2, Cor. 3.7(2)].

Remark 4.10. (Lewittes [74, Thm. 1(b)]) Let $P \in \mathcal{X}(\mathbb{F}_q)$ and $f : \mathcal{X} \to \mathbf{P}^1(\mathbb{F}_q)$ be the $\mathbf{F}_q$-rational function on $\mathcal{X}$ such that $\text{div}_\infty(f) = n_1(P)P$. Then $\mathcal{X}(\mathbb{F}_q) \subseteq f^{-1}(\mathbf{P}^1(\mathbb{F}_q)) = \{P_1\} \cup f^{-1}(\mathbf{F}_q)$ and hence

$$\#\mathcal{X}(\mathbb{F}_q) \leq 1 + qn_1(P).$$

Now from Corollaries 4.3 and 4.7 we see that neither the Hasse-Weil bound nor Serre’s bound is effective to estimate $\#\mathcal{X}(\mathbb{F}_q)$ whenever $g$ is large with respect to $q$. So in general one studies the number

$$N_q(g) := \max\{\#\mathcal{Y}(\mathbb{F}_q) : \mathcal{Y} \text{ curve of genus } g \text{ defined over } \mathbb{F}_q\}.$$

For instance $N_q(0) = q + 1$, and Example 4.9 shows that $N_q(3) = 24$. The study of the actual value of $N_q(g)$ was initiated by Serre [93] who computed $N_q(1)$ and $N_q(2)$. Further properties were proved by Serre himself [94], Lauter [73], and Kresh-Wetherell-Zieve [69]. Tables for $N_q(g)$ with $q$ and $g$ small can be found in van der Geer-van der Vlugt [34].

Definition. A curve $\mathcal{X}$ of genus $g$ and defined over $\mathbb{F}_q$ is called optimal (with respect to $g$ and $q$) if $\#\mathcal{X}(\mathbb{F}_q) = N_q(g)$.

If $q = \ell^2$ and $\mathcal{X}$ is $\mathbf{F}_\ell^2$-maximal then $\mathcal{X}$ is certainly optimal. We already noticed (Example 4.4) that the Hermitian curve $\mathcal{H}$ is $\mathbf{F}_\ell^2$-maximal whose genus attains the bound in Corollary 4.3. Indeed, this property characterizes Hermitian curves:

Theorem 4.11. (Rück-Stichtenoth [87]) A $\mathbf{F}_\ell^2$-maximal curve $\mathcal{X}$ has genus $\ell(\ell - 1)/2$ if and only if $\mathcal{X}$ is $\mathbf{F}_\ell^2$-isomorphic to the Hermitian curve of equation (3.6).
This result follows from Theorem 4.24.

Next we discuss optimal curves for $\sqrt{q} \not\in \mathbb{N}$. Besides some curves of small genus (see above), the only known examples of optimal curves are the Deligne-Lusztig curves $\mathcal{S}$ and $\mathcal{R}$ associated to the Suzuki group $Sz(q)$, $q = 2^{2s+1}$, $s \geq 1$, and to the Ree group $R(q)$, $q = 3^{2s+1}$, $s \geq 1$, respectively [17, Sect. 11]. As a matter of terminology, $\mathcal{S}$ (resp. $\mathcal{R}$) will be called the Suzuki curve (resp. the Ree curve). After the work of Hansen-Stichtenoth [43], Hansen [41], Pedersen [83], Hansen-Pedersen [42], the curves $\mathcal{S}$ and $\mathcal{R}$ can be characterized as follows.

**Theorem 4.12.** The curves $\mathcal{S}$ and $\mathcal{R}$ are the unique curves (up to $\mathbb{F}_q$-isomorphic) $X$ defined over $\mathbb{F}_q$ such that the following three conditions hold:

1. $\#X(\mathbb{F}_q) = q^2 + 1$ (resp. $\#X(\mathbb{F}_q) = q^3 + 1$);
2. $X$ has genus $g_0(q-1)$ (resp. $3g_0(q-1)(q+q_0+1)/2$), where $q_0 := 2^s$ (resp. $3^s$);  
3. $\text{Aut}_{\mathbb{F}_q}(X) = Sz(q)$ (resp. $\text{Aut}_{\mathbb{F}_q}(X) = R(q)$).

Moreover, the Suzuki curve $\mathcal{S}$ (resp. the Ree curve $\mathcal{R}$) is the non-singular model of

$$Y^qZ^{g_0} - YZ^{q+g_0-1} = X^{g_0}(X^q - XZ^{q-1}),$$

(resp.

$$\begin{cases}
Y^qW^{g_0} -YW^{q+g_0-1} = X^{g_0}(X^q - XW^{q-1}) \\
Z^qW^{2g_0} -YW^{q+2g_0-1} = X^{2g_0}(x^q - XW^{q-1})
\end{cases}.$$}

In Sect. 4.3 we prove a stronger version of this theorem for the Suzuki curve.

**Lemma 4.13.** Let $X$ be a curve defined over $\mathbb{F}_q$ such that (1) and (2) in Theorem 4.12 hold. Then $X$ is optimal; moreover:

1. If $q = 2^{2s+1}$, $h_{\mathcal{X}}(t) = (t^2 + 2q_0t + q)^{g_0(q-1)}$;
2. If $q = 3^{2s+1}$, $h_{\mathcal{X}}(t) = (t^2 + 3q_0t + q)^{g_0(q^2-1)(t^2 + q)^{g_0(q-1)(q+3q_0+1)/2}}$.

**Proof.** It is easy to see that Serre’s bound is not effective to bound $\#\mathcal{X}(\mathbb{F}_q)$; in this case one uses the so-called “explicit formula” (4.2) of Weil [93]: (following Stichtenoth [96, p. 183]) Let $h_{\mathcal{X}}(t) = \prod_{i=1}^{g}(t - \alpha_i)(t - \bar{\alpha}_i), \alpha_i = \sqrt{q}e^{\sqrt{-1}b_i}$, and write

$$q^{-i/2}\#\mathcal{X}(\mathbb{F}_q) = q^{i/2} - q^{i/2} - q^{-i/2} \sum_{j=1}^{g}(\alpha_j^i + \bar{\alpha}_j^i);$$

this equation can be rewritten as

$$\#\mathcal{X}(\mathbb{F}_q)c_1q^{-i/2} = c_iq^{i/2} + c_iq^{-i/2} + c_iq^{-i/2}\sum_{j=1}^{g}(\alpha_j^i + \bar{\alpha}_j^i) - (\#\mathcal{X}(\mathbb{F}_q)) - \#\mathcal{X}(\mathbb{F}_q)c_1q^{-i/2},$$

where...
where $c_i \in \mathbb{R}$. Now suppose that $c_1, \ldots, c_m$ are given real numbers. Then from the above equation we obtain:

\[
\# \mathcal{X}(\mathbb{F}_q) \lambda_m(q^{-1/2}) = \lambda_m(q^{1/2}) + \lambda_m(q^{-1/2}) + g - \sum_{j=1}^{g} f_m(q^{-1/2} \alpha_j) - \\
\sum_{i=1}^{m} (\# \mathcal{X}(\mathbb{F}_{q^i}) - \# \mathcal{X}(\mathbb{F}_q)) c_i q^{-i/2},
\]

where $\lambda_m(t) := \sum_{i=1}^{m} c_i t^i$ and $f_m(t) := 1 + \lambda_m(t) + \lambda_m(t^{-1})$. Note that $f_m(t) \in \mathbb{R}$ whenever $t \in \mathbb{C}$ and $|t| = 1$.

Case $q = 2^{2s+1}$ and $g = q_0(q - 1)$. Here we choose $m = 2$, $c_1 = \sqrt{2}/2$, $c_2 = 1/4$. Then $f_2(e^{\sqrt{2} \theta}) = 1 + \sqrt{2} \cos \theta + \cos(2\theta)/2 = (\cos \theta + \sqrt{2}/2)^2 \geq 0$. Then from (4.2) we have

\[
\# \mathcal{X}(\mathbb{F}_q) \lambda_2(q^{-1/2}) \leq \lambda_2(q^{1/2}) + \lambda_2(q^{-1/2}) + g,
\]

so that $\# \mathcal{X}(\mathbb{F}_q) \leq q^2 + 1$, and hence $\mathcal{X}$ is optimal. Moreover, as $\# \mathcal{X}(\mathbb{F}_q) = q^2 + 1$ we must have $f_2(q^{-1/2} \alpha_j) = 0$ by (4.2) so that $\cos \theta_j = -\sqrt{2}/2$. Then $\alpha_j + \alpha_j = -2q_0$ and the result on $h_{\mathcal{X},q}(t)$ follows.

Case $q = 3^{2s+1}$ and $g = 3q_0(q - 1)(q + q_0 + 1)/2$. Here we use $m = 4$, $c_1 = \sqrt{3}/2$, $c_2 = 7/12$, $c_3 = \sqrt{3}/6$, $c_4 = 1/12$. Then $f_4(e^{\sqrt{3} \theta}) = 1 + \sqrt{3} \cos \theta + 7 \cos(2\theta)/6 + \sqrt{3} \cos(3\theta)/3 + \cos(4\theta)/6 = (1 + \sqrt{3} \cos \theta + \cos(2\theta))^2/3 \geq 0$. Then from (4.2)

\[
\# \mathcal{X}(\mathbb{F}_q) \lambda_4(q^{-1/2}) \leq \lambda_4(q^{1/2}) + \lambda_4(q^{-1/2}) + g,
\]

so that $\mathcal{X}(\mathbb{F}_q) \leq q^3 + 1$. Moreover, $1 + \sqrt{3} \cos \theta_j + \cos 2\theta_j = 0$ whenever $\mathcal{X}(\mathbb{F}_q) = q^3 + 1$. Hence $\cos \theta_j = 0$ or $\cos \theta_j = -\sqrt{3}/2$ so that

\[
h_{\mathcal{X},q}(t) = (t^2 + 3q_0 t + q)^4(t^2 + q)^{g-A},
\]

where $A$ is the number of $j$’s such that $\cos \theta_j = -\sqrt{3}/2$. To compute $A$ we use the facts that $a_1 = \# \mathcal{X}(\mathbb{F}_q) - (q + 1) = q^3 - q$ and $a_2g - 1 = q^{g-1}a_1$. We have $a_2g - 1 = h_{\mathcal{X},q}(0) = 3q_0q^{g-1}A$ and hence that $A = q_0(q^2 - 1)$. 

4.1. A $\mathbb{F}_q$-divisor from the Zeta Function. Assume now that $\mathcal{X}(\mathbb{F}_q) \neq \emptyset$, and fix a $\mathbb{F}_q$-rational point $P_0 \in \mathcal{X}$. Let $f = f^{P_0} : P \rightarrow [P - P_0]$ be the canonical map from $\mathcal{X}$ to its Jacobian over $\mathbb{F}_q$, $\mathcal{J} \cong \{ D \in \text{Div}(\mathcal{X}) : \deg(D) = 0 \}/\{ \text{div}(x) : x \in \mathbb{F}_q(\mathcal{X})^* \}$. Let $\Phi_q'$ be the Frobenius morphism on $\mathcal{J}$ induced by $\Phi_q$.

We recall some facts concerning the characteristic polynomial of $\Phi_q'$ which in fact turns out to be the polynomial $h(t) = h_{\mathcal{X},q}(t)$ which was defined in Remark 4.1; see e.g. [77, p. 205], or [76, proof of Thm. 19.1].

For a prime $\ell$ different from $\text{char}(\mathbb{F}_q)$, let $\mathcal{J}_{\ell}$ denote the kernel of the isogeny $\mathcal{J} \rightarrow \mathcal{J}$, $P \mapsto \ell P$. Then one defines the Tate modulo associated to $\mathcal{J}$ as the inverse limit of the groups $\mathcal{J}_{\ell^i}, i \geq 1$, with respect to the maps $\mathcal{J}_{\ell^{i+1}} \rightarrow \mathcal{J}_{\ell^i}$, $P \mapsto \ell P$. We have that
\# \mathcal{J}_\ell = (\ell^i)^{2g} \ [77, \text{p. } 62] \ so \ that \ \mathcal{J}_\ell \ is \ a \ finite \ abelian \ group \ such \ that \ for \ all \ j, \ 1 \leq j \leq i \ it \ contains \ exactly \ (\ell^i)^{2g} \ elements \ of \ order \ \ell^j. \ Therefore

\[ \mathcal{J}_\ell \cong (\mathbb{Z}/\ell^i\mathbb{Z})^{2g} \quad \text{and hence} \quad T_\ell(\mathcal{J}) \cong \mathbb{Z}^{2g}, \]

where \( \mathbb{Z}_\ell \) denotes the \( \ell \)-adic integers. Thus \( T_\ell(\mathcal{J}) \) is a free \( \mathbb{Z}_\ell \)-module of rank \( 2g \). Now clearly \( \Phi_q'(\mathcal{J}_\ell) \subseteq \mathcal{J}_\ell \) and hence \( \Phi_q' \) gives rise to a \( \mathbb{Z}_\ell \)-linear map \( T_\ell(\Phi_q') \) on \( T_\ell(\mathcal{J}) \). Let \( \pi \) be the characteristic polynomial of \( T_\ell(\Phi_q') \). A priori we have that \( \pi \) is a polynomial of degree \( 2g \) with coefficients in \( \mathbb{Z}_\ell \). As a matter of fact, \( \pi \in \mathbb{Z}[t] \ [77, \text{Ch. IV, Thm. 4}], \) and \( \pi = h \) as we mentioned before. In particular, the minimal polynomial \( m \) of \( T_\ell(\Phi_q') \) has integral coefficients. We claim that

\[ m(\Phi_q') = 0 \quad \text{on} \quad \mathcal{J}. \]

To see this, notice that any endomorphism \( \alpha \in \text{End}(\mathcal{J}) : \mathcal{J} \mapsto \mathcal{J} \) acts on \( T_\ell(\mathcal{J}) \) giving rise to a \( \mathbb{Z}_\ell \)-linear map \( T_\ell(\alpha) \). This action is injective because \( \text{End}(\mathcal{J}) \) is torsion free and because of \([77, \text{Ch. IV, Thm. 3}]. \) Now, as \( m(\Phi_q') \in \text{End}(\mathcal{J}) \), we have

\[ 0 = m(T_\ell(\Phi_q')) = T_\ell(m(\Phi_q')) \]

and (4.3) follows. Moreover, it is known that \( \mathbb{Q} \otimes \text{End}(\mathcal{J}) \) is a finite dimensional semisimple algebra over \( \mathbb{Q} \) whose center is \( \mathbb{Q}[\Phi_q'] \ [77, \text{Ch. IV, Cor. 3}], [100, \text{Thm. 2(a)}]. \) In particular, \( \mathbb{Q}[\Phi_q'] \) is semisimple and it is not difficult to see that \( T_\ell(\Phi_q') \) is semisimple; cf. [77, p. 251]. This means that

\[ m(t) = \prod_{i=1}^T h_i(t), \]

where \( h_1(t), \ldots, h_T(t) \) are the irreducibles \( \mathbb{Z} \)-factors of \( h(t) \). Let \( U \) be the degree of \( m(t) \) and let \( b_1, \ldots, b_U \in \mathbb{Z} \) be the coefficients of \( m(t) - t^U; \) i.e,

\[ m(t) = t^U + \sum_{i=1}^U b_it^{U-i}. \]

Thus \( (\Phi_q')^U + \sum_{i=1}^U b_i(\Phi_q')^{U-i} = 0 \) by (4.3). Now we evaluate the left hand side of this equality at \( f(P) = [P - P_0] \), and by using the fact that \( \Phi_q' \circ f = f \circ \Phi_q \) we find that

\[ f(\Phi_q'^U(P)) + \sum_{i=1}^U a_if(\Phi_q'^{-i}(P)) = 0, \quad P \in \mathcal{X}; \]

\[ \text{(4.4)} \]

i.e.,

\[ \Phi_q'^U(P) + \sum_{i=1}^U b_i\Phi_q'^{-i}(P) \sim (1 + \sum_{i=1}^U b_i)P_0 = m(1)P_0. \]

This equivalence is the motivation to define on \( \mathcal{X} \) the linear series

\[ \mathcal{D}_\mathcal{X} := ||m(1)|P_0|, \]

which is clearly independent of \( P_0 \) being \( \mathbb{F}_q \)-rational.
**Problem 4.14.** For a curve $\mathcal{X}$ over $\mathbb{F}_q$, how is the interplay among its $\mathbb{F}_q$-rational points, its Weierstrass points, its $\mathcal{D}_\mathcal{X}$-Weierstrass points, and the support of the $\mathbb{F}_q$-Frobenius divisor of $\mathcal{D}_\mathcal{X}$.

Next we discuss some properties of $\mathcal{D}_\mathcal{X}$.

**Lemma 4.15.**

(1) If $P, Q \in \mathcal{X}(\mathbb{F}_q)$, then $m(1)P \sim m(1)Q$; in particular, $|m(1)|$ is a Weierstrass non-gap at each $P \in \mathcal{X}(\mathbb{F}_q)$.

(2) If $\# \mathcal{X}(\mathbb{F}_q) \geq 2g + 3$, then there exists $P_1 \in \mathcal{X}(\mathbb{F}_q)$ such that $|m(1)| - 1$ and $|m(1)|$ are Weierstrass non-gaps at $P_1$.

**Proof.** (1) It follows immediately from (4.4).

(2) (Following Stichtenoth-Xing [97, Prop. 1]) Let $Q \in \mathcal{X}(\mathbb{F}_q) \setminus \{P_0\}$. From (1), there exists a morphism $x : \mathcal{X} \to \mathbb{P}^1(\mathbb{F}_q)$ with $\text{div}(x) = |m(1)|P_0 - |m(1)|Q$. Let $n$ be the number of $\mathbb{F}_q$-rational points of $\mathcal{X}$ which are unramified for $x$. Let $x^* : \mathcal{X} \to \mathbb{P}^1(\mathbb{F}_q)$ be the separable part of $x$. We have that $\text{div}(x^*) = |m(1)|P_0 - |m(1)|Q$ (here $|m(1)|'$ is the separable degree of $x$) and from the Riemann-Hurwitz applied to $x^*$ we find that

$$2g - 2 \geq |m(1)|'(-2) + 2(|m(1)|' - 1) + (\# \mathcal{X}(\mathbb{F}_q) - n - 2),$$

so that $n \geq \# \mathcal{X}(\mathbb{F}_q) - 2g - 2$. Thus $n \geq 1$ by hypothesis, and hence there exists $\alpha \in \mathbb{F}_q$, $P_1 \in \mathcal{X}(\mathbb{F}_q) \setminus \{P_0, Q\}$ such that $\text{div}(x - \alpha) = P_1 + D - mQ$ with $P_1, Q \notin \text{Supp}(D)$. Let $y \in \mathbb{F}_q(\mathcal{X})$ be such that $\text{div}(y) = |m(1)|Q - |m(1)|P_1$ (cf. (1)). Then $\text{div}(y(x - \alpha)) = D - (|m(1)| - 1)P_1$ and (2) follows.

**Corollary 4.16.**

(1) $\mathcal{D}_\mathcal{X}$ is base-point-free;

(2) If $\# \mathcal{X}(\mathbb{F}_q) \geq 2g + 3$, then $\mathcal{D}_\mathcal{X}$ is simple.

**Proof.** (1) follows by Lemma 4.15 and Example 1.23.

(2) Let $P_1$ be as in Lemma 4.15(2), $\phi$ a morphism associated to $\mathcal{D}_\mathcal{X}$, $f_1, f_2 \in \mathbb{F}_q(\mathcal{X})$ such that $\text{div}_\infty(f_1) = (|m(1)| - 1)P_1$ and $\text{div}_\infty(f_2) = |m(1)|P_1$. Then $[\mathbb{F}_q(\mathcal{X}) : \mathbb{F}_q(f_i)], i = 1, 2$, divides $[\mathbb{F}_q(\mathcal{X}) : \mathbb{F}_q(\phi(\mathcal{X}))]$ and the result follows.

Now we study $(\mathcal{D}_\mathcal{X}, P)$-orders. We let $\epsilon_0 = 0 < \epsilon_1 = 1 < \ldots < \epsilon_N$ (resp. $\nu_0 = 0 < \ldots < \nu_{N-1}$) denote the $\mathcal{D}_\mathcal{X}$-orders (resp. the $\mathbb{F}_q$-Frobenius orders) of $\mathcal{D}_\mathcal{X}$, where $N := \dim(\mathcal{D}_\mathcal{X})$. Notice that $n_N(P) = |m(1)|$ for any $P \in \mathcal{X}(\mathbb{F}_q)$ by Lemma 4.15(1). From Example 1.23 we obtain:

**Lemma 4.17.** For $P \in \mathcal{X}(\mathbb{F}_q)$, the $(\mathcal{D}_\mathcal{X}, P)$-orders are

$$j_{N-i}(P) = n_N(P) - n_i(P), \quad i = 0, 1, \ldots, N.$$

This result (for $i = 1$) and Remark 4.10 yield the following.

**Corollary 4.18.** Let $P \in \mathcal{X}(\mathbb{F}_q)$. If $\# \mathcal{X}(\mathbb{F}_q) > q(|m(1)| - b_U) + 1$, then $j_{N-1}(P) < b_U$. 
Lemma 4.19. Suppose

\begin{equation}
(4.6) \quad b_i \geq 0, \quad i = 1, \ldots, U,
\end{equation}

and let $P \in \mathcal{X}$ such that $\Phi_q^i(P) \neq P$ for $i = 1, \ldots, U$. Then:

1. The numbers $1, b_1, \ldots, b_U$ are $(D_X, P)$-orders;
2. If in addition

\begin{equation}
(4.7) \quad b_1 \geq b_0 := 1 \quad \text{and} \quad b_{i+1} \geq b_i, \quad \text{for} \quad i = 1, \ldots, U - 1,
\end{equation}

then $b_U$ (resp. $b_U - 1$) is a Weierstrass non-gap at $P$ whenever $\Phi_q^{U+1}(P) \neq P$ (resp. $\Phi_q^{U+1}(P) = P$).

Proof. (1) Fix $j \in \{0, 1, \ldots, U\}$, and let $Q \in \mathcal{X}$ such that $q_i(Q) = P$ for $i = 1, \ldots, U$.

We claim that $q_i(Q) \neq P$; otherwise from (4.4) we would have $q_i(P) = P$, a contradiction. This shows (1).

(2) Applying $\Phi_q^j$ to (4.4) we have

\begin{equation}
\Phi_q^j(P) + \sum_{i=1}^{U} b_i \Phi_q^{U-i}(P) \sim m(1)P_0. \tag{\star}
\end{equation}

We claim that $\Phi_q^{U-i}(Q) \neq P$; otherwise from (\star) we would have $\Phi_q^{i-j}(P) = P$, a contradiction. This shows (1).

Remark 4.20. (i) Minimal curves as well as minimal curves with respect to Serre's bound (Remark 4.8) do not satisfy (4.6). However we can still use (4.4) to infer that $\sqrt{q}$ is a non-gap at infinitely many points of the curve provided that the curve is minimal. Indeed, (4.6) reads $\Phi_q(P) - \sqrt{q}P \sim (1 - \sqrt{q})P_0$ so that $\sqrt{q}P \sim (\sqrt{q} - 1)P_0 + \Phi_q(P)$. In particular, if $g \geq \sqrt{q}$, a $F_q$-minimal curve is non-classical.

(ii) The Klein curve (Example 4.9) defined over $F_2$ satisfies (4.6) but not (4.7).

(iii) Other examples as in (i) and (ii) can be found in Carbonne-Henocq [9].

Corollary 4.21. Assume (4.6).

1. If $P \notin \mathcal{X}(F_q)$ and $\mathcal{X}(F_q) = \ldots = \mathcal{X}(F_{q^U})$, then $1, b_1, \ldots, b_U$ are $(D_X, P)$-orders.
2. The numbers $1, b_1, \ldots, b_U$ are $D_X$-orders. In particular, $\dim(D_X) \geq U + 1$ provided that $b_i \neq b_j$ for $i \neq j$;
3. If in addition (4.7) holds and $g \geq b_U$, then $\mathcal{X}$ is non-classical.
Proof. Lemma 4.19(1) implies (1) and (2) since there are infinitely many points $P$ such that $\Phi_q^i(P) \neq P$ for $i = 1, \ldots, U$. To see (3) we take $P \in \mathcal{X}$ such that $\Phi_q^{U+1}(P) \neq P$. Then $b_U \in H(P)$ by Lemma 4.19(2). If $\mathcal{X}$ were classical then $n_1(P) = g + 1$ so that $g < b_U$, a contradiction. \qed

Corollary 4.22. Assume (4.6).

(1) $\epsilon_N = \nu_{N-1} = b_U$;
(2) $\mathcal{X}(\mathbb{F}_q) \subseteq \text{Supp}(R^P)$.

Proof. (1) We have $\epsilon_{N-1} \leq j_{N-1}(P)$ for any $P$ by Corollary 2.10(1); thus $\epsilon_{N-1} < b_U$ by Corollary 4.18. Therefore $\epsilon_N = b_U$ by Corollary 4.21(2), and so

$$\phi^*(L_{N-1}(P)) = \Phi_q^U(P) + \sum_{i=1}^U b_i \Phi_q^{U-i}(P)$$

by (4.4), where $\phi$ is a morphism associated to $D_X$. It follows that $\phi(\Phi_q(P)) \in L_{N-1}(P)$ so that $\nu_{N-1} = \epsilon_N$.

(2) By Lemma 4.17 $j_N(P) = n_N(P) = m(1)$ for each $P \in \mathcal{X}(\mathbb{F}_q)$. Since $m(1) = 1 + \sum_{i=1}^U b_i > b_U = \epsilon_N$ (cf. (1)), the result follows. \qed

Corollary 4.23. Assume (4.7). Then $n_1(P) \leq b_U$ for each $P \in \mathcal{X}(\mathbb{F}_q)$, and equality holds provided that $\#\mathcal{X}(\mathbb{F}_q) \geq qb_U + 1$.

Proof. Let $P \in \mathcal{X}(\mathbb{F}_q)$. By Lemma 2.30 $n_1(P) \leq n_1(Q)$ where $Q \not\in \mathcal{W}$. Therefore $n_1(P) \leq b_U$ by Lemma 4.19(2). Now if $\#\mathcal{X}(\mathbb{F}_q) \geq qb_U + 1$, then $1 + qn_1(P) \geq qb_U + 1$ by Remark 4.10 and the result follows. \qed

4.2. The Hermitian curve. Let $\mathcal{X}$ be a $\mathbb{F}_{\ell^2}$-maximal curve of genus $g$. Recall that $g \leq \ell(\ell+1)/2$ by Corollary 4.3 and that the Hermitian curve is $\mathbb{F}_{\ell^2}$-maximal of genus $\ell(\ell-1)/2$ (cf. Example 3.15). From Lemma 4.2 and (4.5), $\mathcal{X}$ is equipped with the linear series $D_X := [\ell + 1]P_0$. By Corollary 4.16, $D_X$ is simple and base-point-free. We see that $\mathcal{X}$ satisfies (4.7) (and hence (4.6)); in particular $1, \ell$ are $D_X$ orders so that $N := \dim(D_X) \geq 2$.

Theorem 4.24. ([26, Thm. 2.4]) Let $\mathcal{X}$ be a $\mathbb{F}_{\ell^2}$-maximal curve of genus $g$. The following statements are equivalent:

(1) $\mathcal{X}$ is $\mathbb{F}_{\ell^2}$-isomorphic to the Hermitian curve $\mathcal{H}$ of equation (3.6);
(2) $g > (\ell - 1)^2/4$;
(3) $N = 2$.

Proof. (1) implies (2) because the genus of $\mathcal{H}$ is $\ell(\ell - 1)/2$. Assume (2) and suppose that $N \geq 3$. Then Castelnuovo’s genus bound (Remark 1.7) applied to $D_X$ would yield $g \leq (\ell - 1)^2/4$, a contradiction. Finally let $N = 2$. By (4.4) $(\ell + 1)P \sim (\ell + 1)P_0$ for
any \( P \in \mathcal{X}(\mathbf{F}_\ell) \) and hence we can assume that \( \ell, \ell + 1 \in H(P_0) \) by Lemma 4.15(2); in this case, as \( N = 2 \), \( n_1(P_0) = \ell \) and \( n_2(P_0) = \ell + 1 \). Let \( \epsilon_0 = 0 < \epsilon_1 = 1 < \ell \) (resp. \( \nu_0 = 0 < \nu_1 \)) denote the \( D_\mathcal{X} \)-orders (resp. \( \mathbf{F}_\ell \)-orders) of \( \mathcal{X} \). Then \( \epsilon_2 = \nu_1 = \ell \) by Corollary 4.22. Let \( x, y \in \mathbf{F}_\ell(\mathcal{X}) \) such that \( \text{div}_\infty(x) = \ell P_0 \) and \( \text{div}_\infty(y) = (\ell + 1)P_0 \). We have that \( x \) is a separating variable (Lemma 1.24) and therefore

\[
(*) \quad V^{0,1}_{1,x,y;x} = \det \begin{pmatrix} 1 & x^{\ell^2} & y^{\ell^2} \\ 1 & x & y \\ 0 & 1 & D_x^1y \end{pmatrix} = (x - x^{\ell^2})D_x^1y - (y - y^{\ell^2}) = 0 .
\]

**Claim.** There exists \( f \in \mathbf{F}_\ell(\mathcal{X}) \) such that \( D_x^1y = f^\ell \).

To proof this we have to show that \( D_x^i(D_x^1y) = 0 \) \((*)_1\) for \( 1 \leq i < \ell \) by Remark 2.5(ii). We apply \( D_x^1 \) to \((*)\): \((x - x^{\ell^2})D_x^1(D_x^1y) = 0 \) and so \((*)_1\) holds for \( i = 1 \). Suppose that \((*)_1\) is true for \( i = 1, \ldots, j \), \( 1 \leq j \leq \ell - 2 \). We apply \( D_x^{j+1} \) to \((*)\) and using the inductive hypothesis and Remark 2.5(i) we find that \((x - x^{\ell^2})D_x^{j+1}(D_x^1y) = D_x^{j+1}y \). It turns out that

\[
W^{0,1,j+1}_{1,x,y;x} = \begin{pmatrix} 1 & x & y \\ 0 & 1 & D_x^1y \\ 0 & 0 & D_x^{j+1}y \end{pmatrix} = D_x^{j+1}y = 0 ,
\]

since \( \epsilon_2 = \ell \), and the claim follows.

**Claim.** \( \#x^{-1}(x(P)) = \ell \) for \( P \neq P_0 \).

From \((*)\) \( v_{P_0}(D_x^1y) = -\ell^2 \). Let \( t \) be a local parameter at \( P_0 \). Then \( v_{P_0}(D_x^1x) = \ell^2 - \ell - 2 \) since \( D_x^1y = D_x^1xD_x^2y \) by the chain rule (2.3). We have that \( \text{deg}(dx) = 2g - 2 \) (see Example 1.1) and that \( v_p(x) \geq 0 \) for \( P \neq P_0 \). Therefore \( 2g - 2 \geq \ell^2 - \ell - 2 \); i.e., \( g \geq \ell(\ell - 2)/2 \); i.e. \( g = \ell(\ell - 1)/2 \) by Corollary 4.3. It follows that \( v_p(dx) = 0 \) for \( P \neq P_0 \) and so the claim.

We conclude that \( D_x^1y = f^\ell \) with \( \text{div}_\infty(f) = \ell P_0 \); moreover \( f \in \mathbf{F}_q(\mathcal{X}) \) since \( D_x^1y \in \mathbf{F}_q(\mathcal{X}) \). Then \( f = a + bx \) with \( a, b \in \mathbf{F}_\ell \) and \((*)\) gives a relation of type

\[
(y_1^\ell + y_1 - x_1^{\ell+1})^\ell = y_1^\ell + y_1^\ell - x_1^{\ell+1} .
\]

Finally we have that \( y_1^\ell + y_1 - x_1^{\ell+1} = c \in \mathbf{F}_\ell \) and with \( y_2 := y_1 + \lambda, \lambda^\ell + \lambda = a \), we have that \((3.6)\) holds; i.e., \( \mathcal{X} \) is \( \mathbf{F}_\ell \)-isomorphic to \( \mathcal{H} \).

**Corollary 4.25.** ([25]) The genus \( g \) of a \( \mathbf{F}_\ell \)-maximal curve satisfies

\[
either \quad g \leq (\ell - 1)^2/4 \quad \text{or} \quad g = \ell(\ell - 1)/2.\]

**Remark 4.26.** This result was improved in [68] where it is shown that \( g \leq (\ell^2 - \ell + 1)/6 \) whenever \( g < (\ell - 1)^2/4 \).
4.3. The Suzuki curve. Set \( q_0 := 2^s, s \in \mathbb{N}, q := 2q_0^2 \). Let \( X \) be a curve defined over \( \mathbb{F}_q \) of genus \( g \) such that
\[
(4.8) \quad g = q_0(q - 1) \quad \text{and} \quad \#X(\mathbb{F}_q) = q^2 + 1.
\]

The main result of this sub-section is the following theorem which improves Theorem 4.12 for the Suzuki curve \( S \).

**Theorem 4.27.** A curve \( X \) defined over \( \mathbb{F}_q \) is \( \mathbb{F}_q \)-isomorphic to the Suzuki curve \( S \) if and only if (4.8) hold true.

**Problem 4.28.** Can we expect a similar result for the Ree curve?

If (4.8) hold, then \( h_{X,q}(t) = (t^2 + 2q_0t + q)^g \) by Lemma 4.13(1), and from (4.5) we see that \( X \) is equipped with the linear series
\[
D_X = [(q + 2q_0 + 1)P_0] , \quad P_0 \in X(\mathbb{F}_q).
\]

The results of Sect. 4.1 applied to this case are summarized in the following proposition.

Let \( N := \dim(D_X), \epsilon_0 = 0 < \epsilon_1 = 1 < \ldots < \epsilon_N \) (resp. \( \nu_0 = 0 < \ldots < \nu_{N-1} \)) be the \( D_X \)-orders (resp. \( \mathbb{F}_q \)-Frobenius orders) of \( X \).

**Proposition 4.29.** (1) \( j_N(P) = n_N(P) = q + 2q_0 + 1 \) for any \( P \in X(\mathbb{F}_q) \); in addition, there exists \( P_1 \in X(\mathbb{F}_q) \) such that \( n_{N-1}(P_1) = q + 2q_0 \);

(2) \( D_X \) is simple and base-point-free;

(3) \( 2q_0 \) and \( q \) are \( D_X \)-orders so that \( N \geq 3 \);

(4) \( \epsilon_N = \nu_{N-1} = q \);

(5) \( n_1(P) = q \) for any \( P \in X(\mathbb{F}_q) \).

From (5) and (1) above and Lemma 4.17, \( j_{N-1}(P) = j_N(P) - n_1(P) = 2q_0 + 1 \) for any \( P \in X(\mathbb{F}_q) \) so that
\[
2q_0 \leq \epsilon_{N-1} \leq 2q_0 + 1.
\]

**Lemma 4.30.** \( \epsilon_{N-1} = 2q_0 \).

**Proof.** Suppose that \( \epsilon_{N-1} > 2q_0 \). Then \( \epsilon_{N-2} = 2q_0 \) and \( \epsilon_{N-1} = 2q_0 + 1 \). By Corollary 3.9(1) \( \nu_{N-2} \leq j_{N-1}(P) - j_1(P) \leq 2q_0 = \epsilon_{N-2} \), and thus the \( \mathbb{F}_q \)-Frobenius orders of \( D_X \) would be \( \epsilon_0, \epsilon_1, \ldots, \epsilon_{N-2} \), and \( \epsilon_N \). Now from Proposition 3.5(1)
\[
(4.9) \quad v_P(S) \geq \sum_{i=1}^{N} (j_i(P) - \nu_{i-1}) \geq (N - 1)j_1(P) + 1 + 2q_0 \geq N + 2q_0,
\]
for \( P \in X(\mathbb{F}_q) \) so that \( \deg(S) = (\sum_i \nu_i)(2g - 2) + (q + N)(q + 2q_0 + 1) \geq (N + 2q_0)\#X(\mathbb{F}_q) \).

From the identities \( 2g - 2 = (2q_0 - 2)(q + 2q_0 + 1) \) and \( \#X(\mathbb{F}_q) = (q - 2q_0 + 1)(q + 2q_0 + 1) \) we would have
\[
\sum_{i=1}^{N-2} \nu_i = \sum_{i=1}^{N-2} \epsilon_i \geq (N - 1)q_0.
\]
Now, as $\epsilon_i + \epsilon_j \leq \epsilon_{i+j}$ for $i + j \leq N$ by Corollary 2.14,

$$(N - 1)2q_0 = (N - 1)\epsilon_{N-2} \geq 2 \sum_{i=0}^{N-2} \epsilon_i \geq 2(N - 1)q_0,$$

and hence $\epsilon_i + \epsilon_{N-2-i} = \epsilon_{N-2}$ for $i = 0, \ldots, N - 2$. In particular, $\epsilon_{N-3} = 2q_0 - 1$ and by the $p$-adic criterion (Lemma 2.21) we would have $\epsilon_i = i$ for $i = 0, 1, \ldots, N - 3$. Then $N = 2q_0 + 2$. Now from Castelnuovo’s genus bound (Remark 1.7)

$$2g = 2q_0(q - 1) \leq (q + 2q_0 - (N - 1)/2)^2/(N - 1);$$

i.e., $2q_0(q - 1) < (q + q_0)^2/2q_0 = q_0q + q/2 + q_0/2$, a contradiction. \hfill \Box

**Corollary 4.31.** There exists $P_1 \in X(F_q)$ such that

$$\left\{ \begin{array}{l}
    j_1(P_1) = 1 \\
    j_i(P_1) = \nu_{i-1} + 1 \quad \text{if } i = 2, \ldots, N - 1.
\end{array} \right.$$  

*Proof.* Since we already observed that $v_P(S) \geq (N - 1)j_1(P) + 2q_0 + 1 \geq N + 2q_0$ for $P \in X(F_q)$, it is enough to show that there exists $P_1 \in X(F_q)$ such that $v_{P_1}(S) = N + 2q_0$. Suppose that $v_P(S) \geq N + 2q_0 + 1$ for any $P \in X(F_q)$. Then by Theorem 3.13

$$\sum_{i=0}^{N-1} \nu_i \geq q + Nq_0 + 1,$$

so that

$$\sum_{i=0}^{N-1} \epsilon_i \geq Nq_0 + 2,$$

because $\epsilon_1 = 1$, $\nu_{N-1} = q$ and $\nu_i \leq \epsilon_{i+1}$. Then from Corollary 2.14 we would have $N\epsilon_{N-1} \geq 2Nq_0 + 4$; i.e., $\epsilon_{N-1} > 2Nq_0$, a contradiction by Lemma 4.30. \hfill \Box

**Lemma 4.32.**  

(1) $\nu_1 > \epsilon_1 = 1$;  
(2) $\epsilon_2$ is a power of two.

*Proof.* If $\nu_1 > \epsilon_1 = 1$, then $\nu_1 = \epsilon_2$ and it must be a power of two by the $p$-adic criterion (Lemma 2.21): i.e., (1) implies (2). Suppose now that $\nu_1 = 1$. Then from Corollary 4.31 there exists a point $P_1 \in X(F_q)$ such that $j_1(P_1) = 1, j_2(P_1) = 2$; thus

$$H(P_1) \subseteq H := \langle g, q + 2q_0 - 1, q + 2q_0, q + 2q_0 + 1 \rangle,$$

by Proposition 4.29(1)(5) and Lemma 4.17. In particular $g = q_0(q - 1) \leq \tilde{g} := \#(\mathbb{N}_0 \setminus H)$. This is a contradiction as follows immediately from the claim below.

*Claim.* $\tilde{g} = g - q_0^2/4$. 

In fact, \( L := \bigcup_{i=1}^{2q_0-1} L_i \) is a complete system of residues modulo \( q \), where
\[
L_i = \{iq + i(2q_0 - 1) + j : j = 0, \ldots, 2i\} \quad \text{if } 1 \leq i \leq q_0 - 1,
\]
\[
L_{q_0} = \{q_0q + q - q_0 + j : j = 0, \ldots, q_0 - 1\},
\]
\[
L_{q_0+1} = \{(q_0 + 1)q + 1 + j : j = 0, \ldots, q_0 - 1\},
\]
\[
L_{q_0+i} = \{(q_0 + i)q + (2i - 3)q_0 + i - 1 + j : j = 0, \ldots, q_0 - 2i + 1\} \cup \{0, \ldots, q_0 - 1\} \quad \text{if } 2 \leq i \leq q_0/2,
\]
\[
L_{3q_0/2+i} = \{(3q_0/2 + i)q + (q_0/2 + i - 1)(2q_0 - 1) + q_0 + 2i - 1 + j : j = 0, \ldots, q_0 - 2i - 1\} \quad \text{if } 1 \leq i \leq q_0/2 - 1.
\]
Moreover, for each \( \ell \in L \), \( \ell \in H \) and \( \ell - q \notin H \). Hence \( \tilde{g} \) can be computed by summing up the coefficients of \( q \) from the above list (see e.g. [92, Thm. p.3]); i.e.,
\[
\tilde{g} = \sum_{i=1}^{q_0-1} i(2i + 1) + q_0^2 + (q_0 + 1)q_0 + \sum_{i=2}^{q_0/2} (q_0 + i)(2q_0 - 2i + 2) + \sum_{i=1}^{q_0/2-1} (3q_0/2 + i)(q_0 - 2i) = q_0(q - 1) - q_0^2/4.
\]

In the remaining part of this sub-section we let \( P_0 = P_1 \) be a \( \mathbb{F}_q \)-rational point satisfying Corollary 4.31; we set \( n_i := n_i(P_1) \) and \( v := v_{P_1} \).

Lemma 4.32(1) implies \( \nu_i = \epsilon_{i+1} \) for \( i = 1, \ldots, N - 1 \). Therefore from Corollary 4.31 and Lemma 4.17 we have
\[
\begin{cases}
  n_i = 2q_0 + q - \epsilon_{N-i} & \text{if } i = 1, \ldots, N - 2 \\
  n_{N-1} = 2q_0 + q, \quad n_N = 1 + 2q_0 + q.
\end{cases}
\]

Let \( x, y_2, \ldots, y_N \in \mathbb{F}_q(X) \) be such that \( \text{div}_\infty(x) = n_1P_1 \), and \( \text{div}_\infty(y_i) = n_iP_1 \) for \( i = 2, \ldots, N \). The fact that \( \nu_1 > 1 \) means that the following matrix has rank two (see Sect. 3)
\[
\begin{pmatrix}
  1 & x & y_2^q & \ldots & y_r^q \\
  1 & x & y_2 & \ldots & y_r \\
  0 & 1 & D_1 y_2 & \ldots & D_1 y_r
\end{pmatrix}.
\]

In particular,
\[
y_i^q - y_i = D_1^1 y_i(x^q - x) \quad \text{for } i = 2, \ldots, N.
\]

**Lemma 4.33.**
1. \((2g - 2)P\) is canonical for any \( P \in X(\mathbb{F}_q) \); i.e., the Weierstrass semigroup at such a \( P \) is symmetric;
2. Let \( m \in H(P_1) \) such that \( m < q + 2q_0 \). Then \( m \leq q + q_0 \);
3. There exists \( g_i \in \mathbb{F}_q(X) \) such that \( D_1 y_i = g_i^2 \) for \( i, 2, \ldots, N \). Furthermore, \( \text{div}_\infty(g_i) = \frac{qm_i - q^2}{e_2} P_1 \).

**Proof.**
1. By the identity \( 2g - 2 = (2q_0 - 2)(q + 2q_0 + 1) \) and (4.4) we can assume \( P = P_1 \). Now the case \( i = N \) of Eqs. (4.11) implies \( v(dx) = 2g - 2 \) and the result follows since \( v_P(dx) \geq 0 \) for \( P \neq P_1 \).
From (4.10), \( q, q + 2q_0 \) and \( q + 2q_0 + 1 \in H(P_1) \). Then the numbers

\[
(2q_0 - 2)q + q - 4q_0 + j \quad j = 0, \ldots, q_0 - 2
\]

are also non-gaps at \( P_1 \). Therefore, by the symmetry of \( H(P_1) \),

\[
q + q_0 + 1 + j \quad j = 0, \ldots, q_0 - 2
\]

are gaps at \( P_1 \) and the proof follows.

(3) Set \( f_i := D_x^1 y_i \). We have \( D_x^j y_i = (x^q - x)D_x^j f_i + D_x^{(j-1)} f_i \) for \( 1 \leq j < q \) by the product rule applied to (4.11). Then, \( D_x^j f_i = 0 \) for \( 1 \leq j < \epsilon_2 \), because the matrices

\[
\begin{pmatrix}
1 & x & y_2 & \ldots & y_N \\
0 & 1 & D_x^1 y_2 & \ldots & D_x^1 y_N \\
0 & 0 & D_x^2 y_2 & \ldots & D_x^2 y_N 
\end{pmatrix}, \quad 2 \leq j < \epsilon_2
\]

have rank two (see Sect. 2.2). Consequently, as \( \epsilon_2 \) is a power of two by Lemma 4.32(2)), from Remark 2.5(2), \( f_i = g_i^{2i} \) for some \( g_i \in \mathbb{F}_q(\mathcal{X}) \). Finally, from the proof of (1) we have that \( x - x(P) \) is a local parameter at \( P \) if \( P \neq P_1 \). Then, by the election of the \( y_i \)'s, \( g_i \) has no pole but in \( P_1 \), and from (4.11), \( v(g_i) = -(qm_i - q^2)/\epsilon_2 \).

\[\square\]

**Lemma 4.34.** \( N = 4 \) and \( \epsilon_2 = q_0 \).

**Proof.** We know that \( N \geq 3 \). We claim that \( N \geq 4 \) otherwise we would have \( \epsilon_2 = 2q_0 \), \( n_1 = q \), \( n_2 = q + 2q_0 \), \( n_3 = q + 2q_0 + 1 \), and hence \( v(g_2) = -q \) (with \( g_2 \) being as in Lemma 4.33(3)). Therefore, after some \( \mathbb{F}_q \)-linear transformations, the case \( i = 2 \) of (4.11) reads

\[
y_2^q - y_2 = x^{2q_0}(x^q - x)
\]

Now the function \( z := y_2^{q_0} - x^{q_0+1} \) satisfies \( z^q - z = x^{q_0}(x^q - x) \) and we find that \( q_0 + q \) is a non-gap at \( P_1 \) (cf. [43, Lemma 1.8]). This contradiction eliminates the possibility \( N = 3 \).

Let \( N \geq 4 \) and \( 2 \leq i \leq N \). By Lemma 4.33(3) \( (qm_i - q^2)/\epsilon_2 \in H(P_1) \), and since \( (qm_i - q^2)/\epsilon_2 \geq n_{i-1} \geq q_0 \), by (4.10) we have

\[
2q_0 \geq \epsilon_2 + \epsilon_{N-i} \quad \text{for} \ i = 2, \ldots, N - 2.
\]

In particular, \( \epsilon_2 \leq q_0 \). On the other hand, by Lemma 4.33(2) we must have \( n_{N-2} \leq q + q_0 \) and so, by (4.10) we find that \( \epsilon_2 \geq q_0 \); i.e., \( \epsilon_2 = q_0 \).

Finally we show that \( N = 4 \). \( \epsilon_2 = q_0 \) implies \( \epsilon_{N-2} \leq q_0 \). Since \( n_2 \leq q + q_0 \) (cf. Lemma 4.33(2)), by (4.10), we have \( \epsilon_{N-2} \geq q_0 \). Therefore \( \epsilon_{N-2} = q_0 = \epsilon_2 \) so that \( N = 4 \). \[\square\]

**Proof of Theorem 4.27.** Let \( P_1 \in \mathcal{X}(\mathbb{F}_q) \) be as above. By (4.11), Lemma 4.33(3) and Lemma 4.34 we have the following equation

\[
y_2^q - y_2 = g_2^{q_0}(x^q - x),
\]

where \( g_2 \) has no pole except at \( P_1 \). Moreover, by (4.10), \( n_2 = q_0 + q \) and so \( v(g_2) = -q \) (cf. Lemma 4.33(3)). Thus \( g_2 = ax + b \) with \( a, b \in \mathbb{F}_q \), \( a \neq 0 \), and after some \( \mathbb{F}_q \)-linear transformations (as those in the proof of Theorem 4.24) the result follows.
Remark 4.35. (i) From the above computations we conclude that the Suzuki curve $S$ is equipped with a complete, simple and base-point-free $g^4_{q+2q_0+1}$, namely $D_S = |(q + 2q_0 + 1)P_0|$, $P_0 \in S(F_q)$. Such a linear series is an $F_q$-invariant. The orders of $D_S$ (resp. the $F_q$-Frobenius orders) are $0, 1, 2q_0$ and $q$ (resp. $0, q_0, 2q_0$ and $q$).

(ii) There exists $P_1 \in S(F_q)$ such that the $(D_S, P_1)$-orders are $0, 1, q_0 + 1, 2q_0 + 1$ and $q + 2q_0 + 1$ (Corollary 4.31). Now we show that the above sequence is, in fact, the $(D_S, P)$-orders for each $P \in S(F_q)$. To see this, notice that

$$\text{deg}(S) = (3q_0 + q)(2g - 2) + (q + 4)(q + 2q_0 + 1) = (4 + 2q_0)\#S(F_q).$$

Let $P \in S(F_q)$. By (4.9) we conclude that $v_P(S^D) = \sum_{i=1}^{4}(j_i(P) - \nu_{i-1}) = 4 + 2q_0$ and so, by Proposition 3.5(1) that $j_1(P) = 1$, $j_2(P) = q_0 + 1$, $j_3(P) = 2q_0 + 1$, and $j_4(P) = q + 2q_0 + 1$.

(iii) Then, by Lemma 4.17 $H(P)$ contains the semigroup $H := \langle g, q + gq_0, q + 2q_0, q + 2q_0 + 1 \rangle$ whenever $P \in S(F_q)$. Indeed $H(P) = H$ since $\#(\mathbb{N}_0 \setminus H) = g = q_0(q - 1)$ (this can be proved as in the claim in the proof of Lemma 4.32(1); see also [43, Appendix]).

(iv) We have

$$\text{deg}(R) = \sum_{i=0}^{4}\epsilon_i(2g - 2) + 5(q + 2q_0 + 1) = (2q_0 + 3)\#S(F_q),$$

and $v_P(R) = 2q_0 + 3$ for $P \in S(F_q)$ as follows from (i), (ii) and Sect. 2.2. Therefore the set of $D_S$-Weierstrass points of $S$ is equal to $S(F_q)$. In particular, the $(D, P)$-orders for $P \notin S(F_q)$ are $0, 1, q_0, 2q_0$ and $q$.

(v) We can use the above computations to obtain information on orders for the canonical morphism on $S$. By using the fact that $(2q_0 - 2)D_S$ is canonical (cf. Lemma 4.33(1)) and (iv), we see that the set \{a + q_0b + 2q_0c + qd : a + b + c + d \leq 2q_0 - 2\} is contained in the set of orders of $K_S$ at non-rational points. (By considering first order differentials on $S$, similar computations were obtained in [30, Sect. 4].)

(vi) Finally, we remark that $S$ is non-classical for the canonical morphism: We have two different proofs for this fact: loc. cit. and Corollary 4.21(3).

Remark 4.36. (A. Cossidente) Recall that an ovoid in $P^N(F_q)$ is a set of points $P$ no three of which are collinear and such that for each $P$ the union of the tangent lines at $P$ is a hyperplane; see [49]. We are going to related the Suzuki-Tits ovoid $O$ in $P^4(F_q)$ with the $F_q$-rational points of the Suzuki curve $S$.

It is known that any ovoid in $P^4(F_q)$ that contains the point $(0 : 0 : 0 : 0 : 1)$ can be defined by

$$\{(1 : a : b : f(a, b) : af(a, b) + b^2) : a, b \in F_q\} \cup \{(0 : 0 : 0 : 0 : 1)\},$$

where $f(a, b) := a^{2q_0+1} + b^{2q_0}$; cf. [102], [85, p.3].
Let $\phi = (1 : x : y : z : w)$ be the morphism associated to $D_S$ such that $\text{div}_\infty(x) = qP_0$, $\text{div}_\infty(y) = (q + q_0)P_0$, $\text{div}_\infty(z) = (q + 2q_0)P_0$ and $\text{div}_\infty(w) = q + 2q_0 + 1$; see Remark 4.35(iii).

**Claim.** $O = \phi(S(F_q))$.

Indeed we have $\phi(P_0) = (0 : 0 : 0 : 0 : 1)$; in addition the coordinates of $\phi$ can be choosen such that $y^q - y = x^{q_0} + y^{q_0}$, $z := x^{2q_0} + y^{2q_0}$, and $w := xy^{2q_0} + x^{2q_0} + y^{2q_0} + y^q$ (see [43, Sect. 1.7]). For $P \in S(F_q) \setminus \{P_0\}$ set $a := x(P)$, $b := y(P)$, and $f(a, b) := z(a, b)$. Then $w(a, b) = af(a, b) + b^2$ and the claim follows.

**Remark 4.37.** The morphism $\phi$ in the previous remark is an embedding. To see this, as $j_1(P) = 1$ for any $P \in S$ (Remarks 4.35(ii)(iv)), it is enough to show that $\phi$ is injective. We have

$$\tag{4.12} (q + 2q_0 + 1)P_0 \sim q\Phi_2(P) + 2q_0\Phi_q(P) + P$$

so that the points $P \in S$ where $\phi$ could not be injective satisfy either $P \notin S(F_q)$, or $\Phi_q^3(P) = P$ or $\Phi_q^2(P) = P$. Now from the Zeta function of $S$ one sees that $\#S(\mathbb{F}_q) = \#S(\mathbb{F}_q^2) = \#S(\mathbb{F}_q^3)$, and the remark follows.

**Remark 4.38.** From the claim in Remark 4.36, (4.12) and [48] we have

$$\text{Aut}_{F_q}(S) = \text{Aut}_{F_q}(S) \cong \{A \in \text{PGL}(5, q) : AO = O\} .$$

## 5. Plane arcs

In this section we show how to apply Sections 2 and 3 to study the size of plane arcs. The approach is from Hirschfeld-Korchmáros [50], [51] and Voloch [106], [107]. Our exposition follows [36].

A $k$-arc in $\mathbb{P}^2(F_q)$ is a set $K$ of $k$ points no three of which are collinear. It is complete if it is not properly contained in another arc. For a given $q$, a basic problem in Finite Geometry is to find the values of $k$ for which a complete $k$-arc exists. Bose [6] showed that

$$k \leq m(2, q) := \begin{cases} q + 1 & \text{if } q \text{ is odd}, \\ q + 2 & \text{otherwise}. \end{cases}$$

For $q$ odd the bound $m(2, q)$ is attained if and only if $K$ is an irreducible conic [90], [49, Thm. 8.2.4]. For $q$ even the bound is attained by the union of an irreducible conic and its nucleus, and not every $(q + 2)$-arc arises in this way; see [49, Sect. 8.4]. Let $m'(2, q)$ denote the second largest size that a complete arc in $\mathbb{P}^2(F_q)$ can have. Segre [90], [49, Sect. 10.4] showed that

$$\tag{5.1} m'(2, q) \leq \begin{cases} q - \frac{1}{4} \sqrt{q} + \frac{7}{4} & \text{if } q \text{ is odd}, \\ q - \sqrt{q} + 1 & \text{otherwise}. \end{cases}$$
Besides small $q$, namely $q \leq 29$ [11], [49], [53], the only case where $m'(2, q)$ has been determined is for $q$ an even square. Indeed, for $q$ square, examples of complete $(q - \sqrt{q} + 1)$-arcs [5], [12], [18], [23], [60] show that

\begin{equation}
(5.2) \quad m'(2, q) \geq q - \sqrt{q} + 1,
\end{equation}

and so the bound (5.1) for an even $q$ square is sharp. This result has been recently extended by Hirschfeld and Korchmáros [52] who showed that the third largest size that a complete arc can have is upper bounded by $q - 2\sqrt{q} + 6$.

If $q$ is not a square, Segre’s bounds were notably improved by Voloch [106], [107].

If $q$ is odd, Segre’s bound was slightly improved to $m'(2, q) \leq q - \sqrt{q}/4 + 25/16$ by Thas [101]. If $q$ is an odd square and large enough, Hirschfeld and Korchmáros [51] significantly improved the bound to

\begin{equation}
(5.3) \quad m'(2, q) \leq q - \frac{1}{2}\sqrt{q} + \frac{5}{2}.
\end{equation}

Inequalities (5.2) and (5.3) suggest the following problem, which seems to be difficult and has remained open since the 60’s.

**Problem 5.1.** For $q$ an odd square, is it true that $m'(2, q) = q - \sqrt{q} + 1$?

The answer is negative for $q = 9$ and affirmative for $q = 25$ [11], [49], [53]. So Problem 5.1 is indeed open for $q \geq 49$.

5.1. B. Segre’s fundamental theorem: Odd case. We recall a fundamental theorem of Segre which is the link between arcs and curves.

Let $\mathcal{K}$ be an arc in $\mathbf{P}^2(\mathbf{F}_q)$. Segre associates to $\mathcal{K}$ a plane curve $\mathcal{C}$ in the dual plane of $\mathbf{P}^2(\mathbf{F}_q)$. This curve is defined over $\mathbf{F}_q$ and it is called the envelope of $\mathcal{K}$. For $P \in \mathbf{P}^2(\mathbf{F}_q)$, let $\ell_P$ denote the corresponding line in the dual plane. A line $\ell$ in $\mathbf{P}^2(\mathbf{F}_q)$ is called an $i$-secant of $\mathcal{K}$ if $\# \mathcal{K} \cap \ell = i$. The following result summarizes the main properties of $\mathcal{C}$ for the odd case.

**Theorem 5.2.** (B. Segre [90], [49, Sect. 10]) If $q$ is odd, then the following statements hold:

1. The degree of $\mathcal{C}$ is $2t$, with $t = q - k + 2$ being the number of 1-secants through a point of $\mathcal{K}$.
2. All $kt$ of the 1-secants of $\mathcal{K}$ belong to $\mathcal{C}$.
3. Each 1-secant $\ell$ of $\mathcal{K}$ through a point $P \in \mathcal{K}$ is counted twice in the intersection of $\mathcal{C}$ with $\ell_P$; i.e., $I(\mathcal{C}, \ell_P; \ell) = 2$.
4. The curve $\mathcal{C}$ contains no 2-secant of $\mathcal{K}$.
5. The irreducible components of $\mathcal{C}$ have multiplicity at most two, and $\mathcal{C}$ has at least one component of multiplicity one.
For \( k > (2q + 4)/3 \), the arc \( \mathcal{K} \) is incomplete if and only if \( C \) admits a linear component over \( \mathbb{F}_q \). For \( k > (3q + 5)/4 \), the arc \( \mathcal{K} \) is a conic if and only if it is complete and \( C \) admits a quadratic component over \( \mathbb{F}_q \).

Next we show some properties of \( C \). Recall that a non-singular point \( P \) of a plane curve \( A \) is called an inflexion point of \( A \) if \( I(A, \ell; P) > 2 \), with \( \ell \) being the tangent line of \( A \) at \( P \).

**Definition.** A point \( P_0 \) of \( C \) is called special if the following conditions hold:

(i) it is non-singular;
(ii) it is \( \mathbb{F}_q \)-rational;
(iii) it is not an inflexion point of \( C \).

Then, by (i), a special point \( P_0 \) belongs to an unique irreducible component of the envelope which will be called the irreducible envelope associated to \( P_0 \) or an irreducible envelope of \( \mathcal{K} \).

**Lemma 5.3.** Let \( C_1 \) be an irreducible envelope of \( \mathcal{K} \). Then

1. \( C_1 \) is defined over \( \mathbb{F}_q \);
2. if \( q \) is odd and the \( k \)-arc \( \mathcal{K} \), with \( k > (3q + 5)/4 \), is complete and different from a conic, then the degree of \( C_1 \) is at least three.

**Proof.** (1) Let \( C_1 \) be associated to \( P_0 \), let \( \Phi \) be the Frobenius morphism (relative to \( \mathbb{F}_q \)) on the dual plane of \( \mathbb{P}^2(\mathbb{F}_q) \), and suppose that \( C_1 \) is not defined over \( \mathbb{F}_q \). Then, since the envelope is defined over \( \mathbb{F}_q \) and \( P_0 \) is \( \mathbb{F}_q \)-rational, \( P_0 \) would belong to two different components of the envelope, namely \( C_1 \) and \( \Phi(C_1) \). This is a contradiction because the point is non-singular.

(2) This follows from Theorem 5.2(6). \( \Box \)

The next result will show that special points do exist provided that \( q \) is odd and the arc is large enough.

**Proposition 5.4.** Let \( \mathcal{K} \) be an arc in \( \mathbb{P}^2(\mathbb{F}_q) \) of size \( k \) such that \( k > (2q + 4)/3 \). If \( q \) is odd, then the envelope \( C \) of \( \mathcal{K} \) has special points.

**Remark 5.5.** The hypothesis \( k > (2q + 4)/3 \) in the proposition is equivalent to \( k > 2t \), with \( t = q - k + 2 \). Also, under this hypothesis, the envelope \( C \) is uniquely determined by \( \mathcal{K} \), see [49, Thm. 10.4.1(i)].

To prove Proposition 5.4 we need the following lemma.
Lemma 5.6. Let $A$ be a plane curve defined over $\mathbb{F}_q$ and suppose that it has no multiple components. Let $\alpha$ be the degree of $A$ and $s$ the number of its singular points. Then,

$$s \leq \binom{\alpha}{2},$$

and equality holds if $A$ consists of $\alpha$ lines no three concurrent.

Proof. That a set of $\alpha$ lines no three concurrent satisfies the bound is trivial. Let $G = 0$ be the equation of $A$, let $G = G_1 \ldots G_r$ be the factorization of $G$ in $\mathbb{F}_q[X,Y]$, and let $A_i$ be the curve given by $G_i = 0$. For simplicity we assume $\alpha$ even, say $\alpha = 2M$. Setting $\alpha_i := \deg(G_i)$, $i = 1, \ldots, r$ and $I := \sum_{i=1}^{r-1} \alpha_i$ we have $\alpha_r = 2M - I$. The singular points of $A$ arise from the singular points of each component and from the points in $A_i \cap A_j$, $i \neq j$. Recall that an irreducible plane curve of degree $d$ has at most $\frac{d-1}{2}$ singular points, and that $\#(A_i \cap A_j) \leq \alpha_i \alpha_j$, $i \neq j$ (Bézout’s Theorem). So

$$s \leq \sum_{i=1}^{r-1} \binom{\alpha_i - 1}{2} + \binom{2M - I - 1}{2} + \sum_{1 \leq i_1 < i_2 \leq r-1} \alpha_{i_1} \alpha_{i_2} + \sum_{i=1}^{r-1} (2M - I) \alpha_i$$

$$= \sum_{i=1}^{r-1} \frac{\alpha_i^2 - 3 \alpha_i + 2}{2} + \frac{4M^2 - 4MI + I^2 - 6M + 3I + 2}{2} + \sum_{1 \leq i_1 < i_2 \leq r-1} \alpha_{i_1} \alpha_{i_2} + (2M - I)I$$

$$= \frac{1}{2} \left[ \sum_{i=1}^{r-1} \frac{\alpha_i^2}{2} - 3I + 2(r - 1) + 4M^2 - 4MI + I^2 - 6M + 3I + 2 \right]$$

$$+ 2 \sum_{1 \leq i_1 < i_2 \leq r-1} \alpha_{i_1} \alpha_{i_2} + 4MI - 2I^2$$

$$\leq 2M^2 - 3M + \alpha = 2M^2 - M.$$

$\square$

Proof. (Proposition 5.4) Let $F = 0$ be the equation of $C$ over $\mathbb{F}_q$. By Theorem 5.2(5), $F$ admits a factorization in $\mathbb{F}_q[X,Y,Z]$ of type

$$G_1 \ldots G_r H_1^2 \ldots H_s^2,$$

with $r \geq 1$ and $s \geq 0$. Let $A$ be the plane curve given by

$$G := G_1 \ldots G_r = 0.$$

Then $A$ satisfies the hypothesis of Lemma 5.6 and it has even degree by Theorem 5.2(1). From Theorem 5.2(3) and Bézout’s theorem, for each line $\ell_P$ (in the dual plane) corresponding to a point $P \in \mathcal{K}$, we have

$$\#(A \cap \ell_P) \geq M,$$

where $2M = \deg(G)$, and so at least $kM$ points corresponding to unisecants of $\mathcal{K}$ belong to $A$. Since $k > 2t$ (see Remark 5.5) and $2t \geq 2M$, then $kM > 2M^2$ and from Lemma 5.3 we have that at least one of the unisecant points in $A$, says $P_0$, is non-singular. Suppose
that $P_0$ passes through $P \in K$. The point $P_0$ is clearly $\mathbb{F}_q$-rational and $P_0$ is not a point of the curve of equation $H = 0$: otherwise $I(P_0, C \cap \ell_P) > 2$ (see Theorem 5.2(3)). Then, $I(P_0, C \cap \ell_P) = I(P_0, A \cap \ell_P) = 2$ and so $\ell_P$ is the tangent of $C$ at $P_0$. Therefore $P_0$ is not an inflexion point of $C$, and the proof of Proposition 5.4 is complete.

Let $C_1$ be an irreducible envelope associated to a special point $P_0$, and

$$\pi : \mathcal{X} \rightarrow C_1,$$

the non-singular model of $C_1$. Then by Lemma 5.3(1) we can assume that $\mathcal{X}$ and $\pi$ are both defined over $\mathbb{F}_q$. In particular, the linear series $\Sigma_1$ cut out by lines of $\mathbb{P}^2(\mathbb{F}_q)^*$ on $\mathcal{X}$ is $\mathbb{F}_q$-rational. Also, there is just one point $\tilde{P}_0 \in \mathcal{X}$ such that $\pi(\tilde{P}_0) = P$. Let $q$ be odd. Then,

(1) the $(\Sigma_1, \tilde{P}_0)$-orders are 0, 1, 2;

(2) the curve $\mathcal{X}$ is classical with respect to $\Sigma_1$.

Proof. (1) follows from the proof of Proposition 5.4 while (2) from (1) and Corollary 2.10(1).

Remark 5.8. The hypothesis $q$ odd in Lemma 5.7 (as well as in Proposition 5.4) is necessary. In fact, from [23] and [101] follow that the envelope associated to the cyclic $(q - \sqrt{q} + 1)$-arc, with $q$ an even square, is irreducible and $\mathbb{F}_q$-isomorphic to the curve of equation $XY\sqrt{q} + X^{\sqrt{q}}Z + YZ^{\sqrt{q}} = 0$. It is not difficult to see that this curve is $\mathbb{F}_q$-isomorphic to the Hermitian curve $\mathcal{H}$ in Example 3.15 (see e.g. [15, p. 4711]) so that it is $\Sigma_1$ non-classical.

Next consider the following sets:

$$\mathcal{X}_1(\mathbb{F}_q) := \{ P \in \mathcal{X} : \pi(P) \in C_1(\mathbb{F}_q) \},$$

$$\mathcal{X}_{11}(\mathbb{F}_q) := \{ P \in \mathcal{X}_1(\mathbb{F}_q) : j_2^1(P) = 2j_1^1(P) \},$$

$$\mathcal{X}_{12}(\mathbb{F}_q) := \{ P \in \mathcal{X}_1(\mathbb{F}_q) : j_2^1(P) \neq 2j_1^1(P) \},$$

and the following numbers:

$$M_q = M_q(C_1) := \sum_{P \in \mathcal{X}_{11}(\mathbb{F}_q)} j_1^1(P), \quad M'_q = M'_q(C_1) := \sum_{P \in \mathcal{X}_{12}(\mathbb{F}_q)} j_1^1(P),$$

where $0 < j_1^1(P) < j_2^1(P)$ denotes the $(\Sigma_1, P)$-order sequence. We have that

$$M_q + M'_q \geq \#\mathcal{X}_1(\mathbb{F}_q) \geq \#\mathcal{X}(\mathbb{F}_q) \quad \text{and} \quad \#\mathcal{X}_1(\mathbb{F}_q) \geq \#C_1(\mathbb{F}_q).$$

Proposition 5.9. Let $K$ be an arc of size $k$ and $d$ the degree of an irreducible envelope of $K$. For $M_q$ and $M'_q$ as above we have

$$2M_q + M'_q \geq kd.$$
To prove this proposition we first prove the following lemma.

**Lemma 5.10.** Let $K$ be an arc and $C_1$ an irreducible envelope of $K$. Let $Q \in K$ and $A_Q$ be the set of points of $C_1$ corresponding to unisecants of $K$ passing through $Q$. Let $u := \# A_Q$ and $v$ be the number of points in $A_Q$ which are non-singular and inflexion points of $C_1$. Then
\[
2(u - v) + v \geq d,
\]
where $d$ is the degree of $C_1$.

**Proof.** Let $P' \in A_Q$. Suppose that it is non-singular and an inflexion point of $C_1$. Then, from Theorem 5.2(3) and the definition of $A_Q$, we have that $\ell_Q$ is not the tangent line of $C_1$ at $P'$, i.e. we have that $I(\ell_Q, C_1) = 1$. Now suppose that $P'$ is either singular or a non-inflexion point of $C_1$. Then from Theorem 5.2(3) we have $I(\ell_Q, C_1) \leq 2$ and the result follows from Bézout’s theorem applied to $C_1$ and $\ell_Q$.

Proof of Proposition 5.9. Let $Q \in K$ and $A_Q$ be as in Lemma 5.10. Set
\[
\mathcal{Y}_Q := \{P \in \mathcal{X}_1(F_q): \pi(P) \in A_Q\},
\]
and
\[
m(Q) := 2 \sum_{P \in \mathcal{X}_1(F_q) \cap \mathcal{Y}_Q} j_1^1(P) + \sum_{P \in \mathcal{X}_1(F_q) \cap \mathcal{Y}_Q} j_1^1(P).
\]
We claim that $m(Q) \geq d$. Indeed, this claim implies the proposition since, from Theorem 5.2(4),
\[
\mathcal{Y}_Q \cap \mathcal{Y}_Q, = \emptyset \quad \text{whenever} \quad Q \neq Q_1.
\]
To prove the claim we distinguish four types of points in $\mathcal{Y}_Q$, namely
\[
\begin{align*}
\mathcal{Y}_Q^1 := & \{P \in \mathcal{Y}_Q: \pi(P) \text{ is non-singular and non-inflexion point of } C_1\}, \\
\mathcal{Y}_Q^2 := & \{P \in \mathcal{Y}_Q: \pi(P) \text{ is a non-singular inflexion point of } C_1\}, \\
\mathcal{Y}_Q^3 := & \{P \in \mathcal{Y}_Q: \pi(P) \text{ is a singular point of } C_1 \text{ such that } \# \pi^{-1}(\pi(P)) = 1\}, \\
\mathcal{Y}_Q^4 := & \{P \in \mathcal{Y}_Q: \pi(P) \text{ is a singular point of } C_1 \text{ such that } \# \pi^{-1}(\pi(P)) > 1\}.
\end{align*}
\]
Observe that $\mathcal{Y}_Q^1 \subseteq \mathcal{X}_1(F_q)$ and so
\[
m(Q) \geq 2 \sum_{P \in \mathcal{Y}_Q^1} j_1^1(P) + \sum_{P \in \mathcal{Y}_Q^2} j_1^1(P) + \sum_{P \in \mathcal{Y}_Q^3} j_1^1(P) + \sum_{P \in \mathcal{Y}_Q^4} j_1^1(P).
\]
Since $j_1^1(P) > 1$ for all $P \in \mathcal{Y}_Q^4$, the above inequality becomes
\[
m(Q) \geq 2\# \mathcal{Y}_Q^1 + 2\# \mathcal{Y}_Q^2 + \# \mathcal{Y}_Q^3 + \# \mathcal{Y}_Q^4.
\]
Therefore, as to each singular non-cuspidal point of $C_1$ in $\mathcal{A}_Q$ corresponds at least two points in $Y^3_Q$, it follows that

$$m(Q) \geq 2\#\{P' \in \mathcal{A}_Q : P' \text{ is either singular or not an inflexion point of } C_1\} + \#\{P' \in \mathcal{A}_Q : P' \text{ is a nonsingular inflexion point of } C_1\}.$$ 

Then the claim follows from Lemma 5.10 and the proof of Proposition 5.9 is complete.

5.2. The work of Hirschfeld, Korchmáros and Voloch. Throughout the whole sub-section we fix the following notation:

- $q$ is a power of an odd prime $p$;
- $\mathcal{K}$ is a complete arc of size $k$ such that $(3q + 5)/4 < k \leq m'(2, q)$; therefore the degree of any irreducible envelope of $\mathcal{K}$ is at least three by Theorem 5.2(6);
- $P_0$ is a special point of the envelope $\mathcal{C}$ of $\mathcal{K}$ and the plane curve $C_1$ of degree $d$ is an irreducible envelope associated to $P_0$;
- $\pi : \mathcal{X} \to \mathcal{C}_1$ is the normalization of $\mathcal{C}_1$ which is defined over $\mathbb{F}_q$; as a matter of terminology, $\mathcal{X}$ will be also called an irreducible envelope of $\mathcal{K}$.
- $\tilde{P}_0$ is the only point in $\mathcal{X}$ such that $\pi(\tilde{P}_0) = P_0$; $g$ is the genus of $\mathcal{X}$ (so that $g \leq (d - 1)(d - 2)/2$);
- The symbols $M_q$ and $M'_q$ are as in Sect. 5.1;
- $\Sigma_1$ is the linear series $g^2_{2d}$ cut out by lines of $\mathbb{P}^2(\mathbb{F}_q)^*$ on $\mathcal{X}$; $\Sigma_2$ is the linear series $g^5_{2d}$ cut out by conics of $\mathbb{P}^2(\mathbb{F}_q)^*$ on $\mathcal{X}$; then $\Sigma_2 = 2\Sigma_1$. Notice that $\dim(\Sigma_2) = 5$ because $d \geq 3$ and that $\Sigma_1$ and $\Sigma_2$ are base-point-free;
- $S$ is the $\mathbb{F}_q$-Frobenius divisor associated to $\Sigma_2$;
- $j_5(\tilde{P}_0)$ is the 5th positive $(\Sigma_2, \tilde{P}_0)$-order; $\epsilon_5$ is the 5th positive $\Sigma_2$-order; $\nu_4$ is the 4th positive $\mathbb{F}_q$-Frobenius order of $\Sigma_2$.

We apply the results in Sects. 2 and 3 to $\Sigma_1$ and $\Sigma_2$. We have already noticed that the $(\Sigma_1, \tilde{P}_0)$-orders, as well as the $\Sigma_1$-orders, are 0, 1 and 2; see Lemma 5.7. Then, the $(\Sigma_2, \tilde{P}_0)$-orders are 0, 1, 2, 3, 4 and $j_5(\tilde{P}_0)$, with $5 \leq j_5(\tilde{P}_0) \leq 2d$, and the $\Sigma_2$-orders are 0, 1, 2, 3, 4 and $\epsilon_5$ with $5 \leq \epsilon_5 \leq j_5(\tilde{P}_0)$.

Then, we compute the $\mathbb{F}_q$-Frobenius orders of $\Sigma_2$. We apply Proposition 3.5(1) to $\tilde{P}_0$ and infer that this sequence is 0, 1, 2, 3 and $\nu_4$, with

$$\nu_4 \in \{4, \epsilon_5\}.$$ 

Therefore

$$\deg(S) = (6 + \nu_4)(2g - 2) + (q + 5)2d,$$

and

$$v_P(S) \geq 5j_1^2(P), \quad \text{for each } P \in \mathcal{X}_1(\mathbb{F}_q),$$

where $j_1^2(P)$ stands for the first positive $(\Sigma_2, P)$-order.
Claim. $j_1^2(P)$ equals $j_1^1(P)$ (the first positive $(\Sigma_1, P)$-order).

Proof. Let $\Sigma_1 = \{E + \text{div}(f) : f \in \Sigma_1' \setminus \{0\}\}$. From Sect. 2.2 we can assume that $\Sigma_1' = \langle 1, x, y \rangle$ where

\[(*)\quad j_1^1(P) = v_P(E) + v_P(x) \quad \text{and} \quad j_1^1(P) = v_P(E) + v_P(y).
\]

Now $\Sigma_2 = \{2E + \text{div}(f) : f \in \Sigma_2' \setminus \{0\}\}$, where $\Sigma_2' = \langle 1, x, y, xy, x^2, y^2 \rangle$, and there exists $f \in \Sigma_2'$ such that

\[j_1^2(P) = v_P(2E) + v_P(f).
\]

Let $f = a_0 + a_1x + a_2y + a_3x^2 + a_4xy + a_5y^2$. From Lemma 1.4,

\[v_P(2E) = \min\{v_P(1), v_P(x), v_P(y), v_P(x^2), v_P(xy), v_P(y^2)\}.
\]

Suppose that $0 \leq v_P(x)$ and $0 \leq v_P(y)$. Then $v_P(2E) = 0$ so that $v_P(f) = j_1^2(P) > 0$ and hence $a_0 = 0$. Then the result follows from $(*)$. Now suppose that $0 > v_P(x)$ or $0 > v_P(y)$. Then $v_P(2E) < 0$ and hence $a_0 \neq 0$ for some $i \in \{1, \ldots, 5\}$. Then the result follows from $(*)$ and the fact that $v_P(f) \geq \min\{v_P(x), v_P(y), v_P(x^2), v_P(xy), v_P(y^2)\}$.

We then have

\[\deg(S) \geq 5(M_q + M'_q),\]

where $M_q$ and $M'_q$ were defined in (5.4).

Proposition 5.11. Let $K$ be a complete arc of size $k$ such that $(3q + 5)/4 < k \leq m'(2, q)$. Then

\[k \leq \min\left\{q - \frac{1}{4}\nu_4 + \frac{7}{4}, \frac{28 + 4\nu_4}{29 + 4\nu_4}q + \frac{32 + 2\nu_4}{29 + 4\nu_4}\right\},
\]

where $\nu_4$ is the 4th positive $\text{F}_q$-Frobenius order of the linear series $\Sigma_2$ defined on an irreducible envelope of $K$.

Proof. From the computations above and Proposition 5.9,

\[\deg(S) = (6 + \nu_4)(2g - 2) + (q + 5)2d \geq 5(M_q + M'_q) \geq \frac{5}{2}kd.
\]

Now $d(d - 3) \geq 2g - 2$ and $d \leq 2t = 2(q + 2 - k)$ (Theorem 5.2(1)). Then $k(2g + \nu_4) \leq (28 + 4\nu_4)q + (32 + 2\nu_4)$. On the other hand, $\nu_4 \leq j_5(P_0) - 1 \leq 2d - 1$ (Proposition 3.5(1)) and hence $k \leq q - \frac{a_0}{4} + \frac{4}{4}.

Next we consider separately the cases $\nu_4 = 4$ and $\nu_4 = e_5$.

Case $\nu_4 = 4$. In this case, the corresponding irreducible envelope will be called Frobenius classical. Proposition 5.11 becomes the following.

Corollary 5.12. Let $K$ be a complete arc of size $k$ such that $(3q + 5)/4 < k \leq m'(2, q)$. Suppose that $K$ admits a Frobenius classical irreducible envelope. Then

\[k \leq \frac{44}{45}q + \frac{40}{45}.
\]
The bound in the corollary holds in the following cases:

(A) (Voloch [107]) Whenever $q = p$ is an odd prime;

(B) (Giulietti [35]) The arc is cyclic of Singer type whose size $k$ satisfies $2k \equiv -2, 1, 2, 4 \pmod{p}$, where $p > 5$.

For the sake of completeness let us prove (A): Let $\mathcal{C}_1$ be an irreducible envelope of $\mathcal{K}$ and $d$ the degree of $\mathcal{C}_1$. If $p < 2d$, then $p < 4t = 4(p + 2 - k)$ so that $k < (3p + 8)/4$ and the result follows. So let $p \geq 2d$. Then from Remark 3.10 we have that $\mathcal{C}_1$ is Frobenius classical and (A) follows from Proposition 5.11.

Next we show that, for $q$ square and $k = m'(2, q)$, Corollary 5.12 can only hold for $q$ small.

**Corollary 5.13.** Let $\mathcal{K}$ be an arc of size $m'(2, q)$ and suppose that $q$ is a square. Then,

1. if $q > 9$, $\mathcal{K}$ has irreducible envelopes;
2. if $q > 43^2$, any irreducible envelope of $\mathcal{K}$ is Frobenius non-classical.

**Proof.** (1) As we mentioned in (5.2), $m'(2, q) \geq q - \sqrt{q} + 1$. Since $q - \sqrt{q} + 1 > (2q + 4)/3$ for $q > 9$, (1) follows from Proposition 5.4.

(2) If existed a Frobenius classical irreducible envelope of $\mathcal{K}$, then from Lemma 5.14 and (5.2) we would have

$$q - \sqrt{q} + 1 \leq m'(2, q) \leq 44q/45 + 40/45,$$

so that $q \leq 43^2$. \qed

**Case** $\nu_4 = \epsilon_5$. Here, from Lemma 3.16 we have that $p$ divides $\epsilon_5$. More precisely we have the following result.

**Lemma 5.14.** Either $\epsilon_5$ is a power of $p$ or $p = 3$ and $\epsilon_5 = 6$.

**Proof.** We can assume $\epsilon_5 > 5$. If $\epsilon_5$ is not a power of $p$, by the $p$-adic criterion (Lemma 2.21) we have $p \leq 3$ and $\epsilon = 6$. \qed

From Proposition 5.11, the case $\nu_4 = \epsilon_5 = 6$ provides the following bound:

**Lemma 5.15.** Let $\mathcal{K}$ be a complete arc of size $k$ such that $(3q + 5)/4 < k \leq m'(2, q)$. Suppose that $\mathcal{K}$ admits an irreducible envelope such that $\nu_4 = \epsilon_5 = 6$. Then $p = 3$ and

$$k \leq \frac{52}{53}q + \frac{44}{53}.$$

As in the case $\nu_4 = 4$, for $q$ an even power of 3 and $k = m'(2, q)$ the case $\nu_4 = \epsilon_5 = 6$ occur only for $q$ small. More precisely, we have the following result.

**Corollary 5.16.** Let $\mathcal{K}$ be an arc of size $m'(2, q)$. Suppose that $q$ is an even power of $p$ and that $\mathcal{K}$ admits an irreducible envelope with $\nu_4 = \epsilon_5 = 6$. Then $p = 3$ and $q \leq 3^6$. 

Proof. From the p-adic criterion (Lemma 2.21), $p = 3$. Then from Proposition 5.11 and (5.2) we have
\[ q - \sqrt{q} + 1 \leq m'(2, q) \leq 52q/53 + 44/53, \]
and the result follows.

From now on we assume
\[ \nu_4 = \epsilon_5 = \text{a power of } p. \]
Then, the bound
\[ (5.5) \quad k \leq q - \frac{1}{4} \nu_4 + \frac{7}{4} \]
in Proposition 5.11 and Segre’s bound (5.1) provide motivation to consider three cases according as $\nu_4 > \sqrt{q}$, $\nu_4 < \sqrt{q}$, or $\nu_4 = \sqrt{q}$.

Case $\nu_4 > \sqrt{q}$. Since $\nu_4$ is a power of $p$, here we have that $\nu^2 \geq pq$ and so from (5.5) the following holds:

**Lemma 5.17.** Let $K$ be a complete arc of size $k$ such that $(3q + 5)/4 < k \leq m'(2, q)$. Suppose that $K$ admits an irreducible envelope such that $\nu_4$ is a power of $p$ and that $\nu_4 > \sqrt{q}$. Then
\[
k \leq \begin{cases} 
q - \frac{1}{4} \sqrt{pq} + \frac{7}{4} & \text{if } q \text{ is not a square}, \\
q - \frac{1}{4} \nu_4 \sqrt{q} + \frac{7}{4} & \text{otherwise}.
\end{cases}
\]
If $q$ is a square and $k = m'(2, q)$, then $\nu_4 > \sqrt{q}$ can only occur in characteristic 3:

**Corollary 5.18.** Let $K$ be an arc of size $m'(2, q)$. Suppose that $q$ is an even power of $p$ and that $K$ admits an irreducible envelope with $\nu_4$ a power of $p$ and $\nu_4 > \sqrt{q}$. Then $p = 3$, $\nu_4 = 3\sqrt{q}$, and
\[ k \leq q - \frac{3}{4} \sqrt{q} + \frac{7}{4}. \]

Proof. From Lemma 5.17 and (5.2) follow that $\sqrt{q}(p - 4) \leq 3$ and so that $p = 3$. From $\nu_4 \leq 2d - 1$ and $2d \leq 4t = 4q + 4m'(2, q) \leq 4\sqrt{q} + 4$ we have that $\nu_4 \leq 4\sqrt{q} + 3$ and it follows the assertion on $\nu_4$. The bound on $k$ follows from Lemma 5.17.

Case $\nu_4 < \sqrt{q}$. Let
\[ F(x) := (2x + 32 - q)/(4x + 29). \]
Then the bound
\[ k \leq \frac{28 + 4\nu_4}{29 + 4\nu_4} q + \frac{32 + 2\nu_4}{29 + 4\nu_4} \]
in Proposition 5.11 can be written as
\[ (5.6) \quad k \leq q + F(\nu_4). \]
For $x > 0$, $F(x)$ is an increasing function so that

$$F(\sqrt{q/p}) = -\frac{1}{4}\sqrt{pq} + \frac{29}{10}p + \frac{1}{2} + R \quad \text{if } q \text{ is not a square,}$$
$$F(\sqrt{q/p}) = -\frac{1}{4}p\sqrt{q} + \frac{29}{10}p^2 + \frac{1}{2} + R \quad \text{otherwise},$$

where

$$R = \begin{cases} -\frac{841p-280}{16(\sqrt{q/p}+29)} & \text{if } q \text{ is not a square,} \\ -\frac{841p^2-280}{16(\sqrt{q/p}+29)} & \text{otherwise}. \end{cases}$$

Then from (5.6) and since $R < 0$ we have the following result.

**Lemma 5.19.** Let $K$ be a complete arc of size $k$ such that $(3q + 5)/4 < k \leq m'(2, q)$. Suppose that $K$ admits an irreducible envelope such that $\nu_4$ is a power of $p$ and that $\nu_4 < \sqrt{q}$. Then

$$k < \begin{cases} q - \frac{1}{4}\sqrt{pq} + \frac{29}{10}p + \frac{1}{2} & \text{if } q \text{ is not a square,} \\ q - \frac{1}{4}p\sqrt{q} + \frac{29}{10}p^2 + \frac{1}{2} & \text{otherwise.} \end{cases}$$

**Corollary 5.20.** Let $K$ be a complete arc of size $m'(2, q)$. Suppose that $q$ is an even power of $p$ and that $K$ admits an irreducible envelope with $\nu_4$ a power of $p$ and $\nu_4 < \sqrt{q}$. Then one of the following statements holds:

1. $p = 3, \nu_4 = \sqrt{q}/3$, and $m'(2, q)$ satisfies Lemma 5.19.
2. $p = 5, q = 5^4, \nu_4 = 5$, and $m'(2, 5^4) \leq 613$;
3. $p = 5, q = 5^6, \nu_4 = 5^2$, and $m'(2, 5^6) \leq 15504$;
4. $p = 7, q = 7^4, \nu_4 = 7$, and $m'(2, 7^4) \leq 2359$.

**Proof.** Let $q = p^{2e}$; so $e \geq 2$ as $p \leq \nu_4 < p^e$. From (5.2) and Lemma 5.19 we have that

$$(p - 4)p^{e}/4 < 29p^2/16 - 0.5,$$

so that $p \in \{3, 5, 7, 11\}$.

Let $p = 3$. If $\nu_4 \leq \sqrt{q}/9$ (so $e \geq 4$), then from (5.2) and $m'(2, q) \leq q + F(\sqrt{q}/9)$ we would have that

$$q - \sqrt{q} + 1 \leq q - 9\sqrt{q}/4 + 2357/16 - 67841/16(43^{e-2} + 29),$$

which is a contradiction for $e \geq 4$.

Let $p = 11$. Then $p^e \leq 125$ and $e = 2$ and $\nu_4 = 11$. Thus from Proposition 5.11 we have $m'(2, 11^4) \leq 11^4 + F(11)$, i.e. $m'(2, 11^4) \leq 14441$. This is a contradiction since by (5.2) we must have $m'(2, 11^4) \geq 14521$. This eliminates the possibility $p = 11$.

The other cases can be handled in an analogous way. □

**Case** $\nu_4 = \sqrt{q}$. In this case, according to (5.5), we just obtain Segre’s bound (5.1).
Next we study geometrical properties of irreducible envelopes associated to large complete arcs in \( \mathbf{P}^2(\mathbb{F}_q) \), \( q \) odd. In doing so we use the bounds obtained above and divide our study in two cases according as \( q \) is a square or not.

**Case \( q \) square.** Let \( \mathcal{X} \) be an irreducible envelope associated to an arc of size \( m'(2,q) \). Then from Lemma 5.7, and Corollaries 5.13, 5.16, 5.18, 5.20, we have the following result.

**Proposition 5.21.** If \( q \) is an odd square and \( q > 43^2 \), then \( \mathcal{X} \) is \( \Sigma_1 \)-classical. The \( \Sigma_2 \)-orders are 0, 1, 2, 3, 4, \( \epsilon_5 \) and the \( \mathbb{F}_q \)-Frobenius \( \Sigma_2 \)-orders are 0, 1, 2, 3, \( \nu_4 \), with \( \epsilon_5 = \nu_4 \), where also one of the following holds:

1. \( \nu_4 \in \{ \sqrt{q}/3, 3\sqrt{q} \} \) for \( p = 3 \);
2. \( (\nu_4, q) \in \{ (5, 5^4), (5^2, 5^6), (7, 7^4) \} \);
3. \( \nu_4 = \sqrt{q} \) for \( p \geq 5 \).

**Case \( q \) non-square.** In this case there is no analogue to bound (5.2). From Corollary 5.12 and Lemmas 5.15, 5.17, 5.19, and taking into consideration (5.6) we have the following result.

**Proposition 5.22.** Let \( q > 43^2 \) and \( q = p^{2e+1}, e \geq 1 \). Then, apart from the values on \( \nu_4 \), the curve \( \mathcal{X} \), \( \nu_4 \) and \( \epsilon_5 \) are as in Proposition 5.21. In this case

\[ m'(2,q) > q - 3\sqrt{pq}/4 + 7/4 \]

implies

1. \( \nu_4 = \sqrt{pq}/p \);
2. \( m'(2,q) < q - \sqrt{pq}/4 + 29p/16 + 1/2 \).

In particular, our approach just gives a proof of Segre’s bound (5.1) and Voloch’s bound [107]. However, both propositions above show the type of curves associated to large complete arcs. The study of such curves, for \( q \) square and large enough, allowed Hirschfeld and Korchmáros [50], [51] to improve Segre’s bound (5.1) to the bound in (5.3).

Next we stress here the main ideas from [51] necessary to deal with Problem 5.1. Due to Proposition 5.9, the main strategy is to bound from above the number \( 2M_q + M'_q \) (which is defined via (5.4)). For instance, if one could prove that

\[ 2M_q + M'_q \leq d(q - \sqrt{q} + 1), \tag{5.7} \]

where \( d \) is the degree of the irreducible envelope whose normalization is \( \mathcal{X} \), then from Proposition 5.9 would follow immediately an affirmative answer to Problem 5.1. However, since we know the answer to be negative for \( q = 9 \) and \( d \leq 2t = 2(q + 2 - m'(2,q)) \), then one can assume that \( d \) is bounded by a linear function on \( \sqrt{q} \) and should expect to prove (5.7) only under certain conditions on \( q \).
Lemma 5.23. Let $q$ be an odd square. If (5.7) holds true for $d \leq 2\sqrt{q} - \alpha$ with $\alpha \geq 0$, then $m'(2, q) < q - \sqrt{q} + 2 + \alpha/2$. In particular, if (5.7) holds true for $d \leq 2\sqrt{q}$, then the answer to Problem 5.1 is positive; i.e., $m'(2, q) = q - \sqrt{q} + 1$.

Proof. If $m'(2, q) \geq q - \sqrt{q} + 2 + \alpha/2$, then from $d \leq 2(q + 2 - m'(2, q))$ we would have that $d \leq 2\sqrt{q} - \alpha$ and so, from Proposition 5.9 and (5.7), that $m'(2, q) \leq q - \sqrt{q} + 1$, a contradiction. \hfill $\Box$

Now, in [50], (5.7) is proved for $d \leq \sqrt{q} - 3$ and $q$ large enough, and so (5.3) follows. More precisely we have the following.

Theorem 5.24. (Hirschfeld-Korchmáros [51, Thm. 1.3]) Let $q$ be a square, $q > 23^2$, $q \neq 3^6$. Let $3 \leq d \leq \sqrt{q} - 3$. Suppose that $\Sigma_1$ is classical, that $0, 1, 2, 3, 4, \sqrt{q}$ are the $\Sigma_2$-orders, and that $0, 1, 2, 3, \sqrt{q}$ are the $\mathbf{F}_q$-Frobenius orders of $\Sigma_2$. Then (5.7) holds.

Proof. (Sketch) Suppose that $2M_q + M'_q \geq d(q - \sqrt{q} + 1)$. We are going to show that $2M_q + M'_q = d(q - \sqrt{q} + 1)$. Notice that $d \geq (\sqrt{q} + 1)/2$ by Corollary 3.9(1). Let $\phi = (f_0 : \ldots : f_3)$ be a morphism associated to $\Sigma_2$. From Lemma 2.9 there exist $z_0, \ldots, z_5 \in \mathbf{F}_q(\mathcal{X})$, not all zero, such that $\sum_{i=0}^5 z_i^q f_i = 0$. Set

$$\mathcal{Z} := (z_0 : \ldots : z_5)(\mathcal{X}).$$

(This curve is related to the dual curve of $\phi(\mathcal{X})$ since it is easy to see that $\sum_{i=0}^5 z_i^q(P)X_i = 0$ is the hyperplane tangent at $P$ for infinitely many $P$'s.)

We have [51, Props. 8.3, 8.4, 8.5]

(I) $\sqrt{q}\deg(\mathcal{Z}) \leq d(2d + q + 3) - (2M_q + M'_q)$;

(II) $\deg(\mathcal{Z}) \geq \sqrt{q}j_1(P)$ for any $P \in \mathcal{X}$;

(III) $\deg(\mathcal{Z}) \geq 2\sqrt{q}$ whenever $\mathcal{C}_1$ is singular.

It follows from (I) and (II) that $j_1(P) \leq 2$ since $d \leq \sqrt{q} - 3$. Now from Corollary 2.18 and the hypothesis on $d$ there are three possibilities for $(\Sigma_1, P)$-orders:

(A) $j_2(P) = 2j_1(P)$;

(B) $j_2(P) = (\sqrt{q} + j_1(P))/2$;

(C) $j_2(P) = \sqrt{q} - j_1(P)$.

We see that points of type (C) cannot occur since $j_1(P) \leq 2$ and $d \leq \sqrt{q} - 3$. Now from the proof of [51, Prop. 9.4] we have that

$$\sqrt{q}\deg(\mathcal{Z}) = 2(dq + d - 2M_q - M'_q) \leq 2d\sqrt{q},$$

so that $\deg(\mathcal{Z}) < 2\sqrt{q}$ as $d \leq \sqrt{q} - 3$. It follows from (III) that $\mathcal{C}_1$ is non-singular; i.e., $\mathcal{X} = \mathcal{C}_1$. In particular the $\Sigma_1$-Weierstrass points are of type (B) and we have

$$\deg(R_1) = 3d(d - 2) = (\sqrt{q} - 3)/3\tau,$$
where $R_1$ is the ramification divisor of $\Sigma_1$ and $\tau$ is the number of points of type (B). Now we use the following relation between $\deg(Z)$ and $\tau$ [51, Prop. 9.3]:

$$\text{(IV)} \quad 3\deg(Z) = 2\tau.$$ 

Since we already notice that $\deg(Z) \leq 2d$ it follows that $d \leq (\sqrt{q} + 1)/2$; i.e., $d = (\sqrt{q} + 1)/2$. Next we show that $\tau = M'_q$. For $P$ of type (B), the $(\Sigma_2, P)$-orders are 0, 1, 2, $(\sqrt{q} + 1)/2, (\sqrt{q} + 3)/2, \sqrt{q} + 1$. Suppose that $P \not\in X(F_q)$. Then $2\ell_P$ is the tangent hyperplane $L_4(P)$ at $P$ with respect to $\Sigma_2$, where $\ell_P$ is the tangent line at $P$ with respect to $\Sigma_1$. It is easy to see that $F_q(P) \in L_4(P)$ so that $F_q(P) \not\in \ell_P$. This implies $d > (\sqrt{q} + 1)/2$, a contradiction. Thus $M'_q = 3(\sqrt{q} + 1)/2$. Finally by means of

$$\deg(S_1) = d(q + d - 1) = 2M_q + \frac{\sqrt{q} + 1}{2}M'_q,$$

where $S_1$ is the $F_q$-Frobenius divisor associated to $\Sigma_1$, we find that $M_q = (\sqrt{q} + 1)(q - \sqrt{q} - 2)/4$, and one easily checks that $2M_q + M'_q = d(q - \sqrt{q} + 1)$. 

**Remark 5.25.** The plane curve $X$ of degree $d = (\sqrt{q} + 1)/2$ in the above proof satisfies

$$\#X(F_q) = M_q + M'_q = q + 1 + \sqrt{q}(d - 1)(d - 2);$$

i.e., it is $F_q$-maximal. If $q \geq 121$, such a curve is $F_q$-isomorphic to the Fermat curve $X((\sqrt{q} + 1)/2 + Y((\sqrt{q} + 1)/2 = 0$; see [13].

Recently, Aguglia and Korchmáros [1] proved a weaker version of (5.7) for $d = \sqrt{q} - 2$ and $q$ large enough, namely

$$2M_q + M'_q \leq d(q - \sqrt{q}/2 - 9/2) - 3.$$

From this inequality and Proposition 5.9 one slightly improves (5.3) to $m'(2, q) \leq q - \sqrt{q}/2 - 11/2$ whenever $d = \sqrt{q} - 2$ and $q$ is large enough. Therefore the paper [1], as well as [50] or [51], is a good guide toward the proof of (5.7) for $\sqrt{q} - 2 \leq d \leq 2\sqrt{q}$.
